37	M., 3 wks.	Complete; left harelip.	1. Dec. 15th, 1905. 2. Mar. 23rd, 1906. 3. Aug. 29th, 1907 (lip only).	— Hole remained in soft palate. —	Hole on right side, at junction of hard and soft palates. Soft palate very short and very little movable.	Poor, but usually intelligible; trouble especially with <i>th</i> and <i>s</i> .	Seen Oct., 1911.
38	F., 10 wks.	Soft, and posterior half of hard palate.	Dec. 19th, 1905.	Complete closure (?)	Died at age of 6 months from pneumonia. Was to have had a second operation.		Interview with mother Dec., 1914. Seen Nov., 1911.
39	M., 4 mos.	Complete; double harelip.	1. Jan. 2nd, 1906. 2. Mar. 13th, 1906 (lip only).	Healed.	Hard palate healed; premaxilla in position but quite loose, with a fissure on each side of it. Soft palate widely cleft; remaining tissues scarred and deformed, and do not move much. Teeth very carious.	Bad; quite unintelligible as a rule and very nasal.	Seen Nov., 1911.
40	M., 6 wks.	Soft, and posterior two-thirds of hard palate 5/8-3/4 in. wide.	1. Jan. 5th, 1906. 2. Mar. 20th, 1906. 3. July 13th, 1906.	— Healed.	Died from convulsions 7 months after last operation. Palate was completely healed.		Letter from father Dec., 1912.
41	F., 7 wks.	Soft, and posterior two-thirds of hard palate 1/2 in. wide.	Jan. 5th, 1906.	Healed.	Cannot be traced.		—
42	M., 4 wks.	Soft, and posterior half of hard palate; right incomplete harelip.	Jan. 9th, 1906.	Healed.	"Palate: We have never had any trouble in this respect. Teeth: Are somewhat irregularly placed, and a few have required the attention of the dentist."	Fair; can be understood if he speaks deliberately. Often unintelligible if he speaks fast. Trained for a year, and improving.	Letter from father Nov., 1911.
43	M., 3 wks.	Complete; left harelip.	1. Jan. 16th, 1906. 2. April 3rd, 1906.	Anterior half did not hold.	Death 5 days after second operation; persistent vomiting.		—
44	M., 1½ yrs.	Soft, and posterior half of hard palate 1/2 inch wide.	Jan., 1906.	Healed.	Hard palate healed. Soft palate short, movable; posterior 1/2 inch is ununited.	Very bad; usually unintelligible; special trouble with <i>b</i> , <i>d</i> , <i>k</i> .	Seen Sept., 1911.
45	F., 5 wks.	Soft, and posterior half of hard palate; left incomplete harelip.	Jan. 26th, 1906.	Healed.	Healed; hard palate ridged and grooved; soft palate fairly well-formed; no uvula. Teeth rather irregular—otherwise not bad.	Child could not be made to speak. Mother says she speaks fairly, though strangers cannot at first always understand her.	Seen Oct., 1912.
46	M., 2 wks.	Complete; left harelip.	1. Feb. 2nd, 1906. 2. Apr. 13th, 1906.	Posterior third and a small gap anteriorly remained unjoined. Diarrhoea.	Death about May 8th, 1906.		—

TABLE III.—100 Consecutive Cases of Cleft Palate treated by Arbuthnot Lane's Operation, with their Immediate and Remote Results—(Continued).

No.	Sex and age.	Extent of cleft.	Operations.	Immediate result.	Ultimate result.		Last report.
					Palate, &c.	Speech.	
47	F., 11 yrs.	Soft, and posterior half of hard palate $\frac{1}{2}$ inch wide. Harelip cured.	Feb. 6th, 1906.	Failed.	"The palate is still open, except a small part at the back."	"She speaks fairly plain with us, but strangers do not understand her, and she has had no training."	Letter from mother Nov., 1911.
48	M., 6 wks.	Not stated. Child cyanosed; loud heart murmur; thrush and diarrhoea which were treated before operation for nearly 3 weeks.	Feb. 27th, 1906.	—	Death from broncho-pneumonia. April 3rd, 1906.		—
49	M., 7 yrs.	Soft, and posterior half to two-thirds of hard palate.	Feb. 23rd, 1906.	Failure.	Cleft widely open; very little tissue at sides of cleft.	Poor; markedly nasal. Mother says he can be understood at school.	Seen Sept., 1912.
50	F., 6 wks.	Soft, and posterior three-quarters of hard palate; left harelip.	Feb. 16th, 1906.	Failure.	Death from pneumonia the day after return from hospital.		Conversation with mother Oct., 1912.
51	M., 4 wks.	Complete; left harelip.	1. Feb. 23rd, 1906. 2. Feb. 16th, 1907 (lip only).	Not stated.	Hole, about 5 mm. diameter, on left side at junction of hard and soft palates. Soft palate healed, but short and almost motionless. Teeth irregular; 3 are carious.	Markedly nasal. Ordinary speech only with difficulty intelligible, though separate words quite intelligible.	Seen Nov., 1911.
52	M., 5 wks.	Complete; left harelip.	Feb. 27th, 1906.	Suppuration; abscesses in left cheek and in sub-maxillary regions. Death.	—		—
53	F., 3 mos.	Soft palate.	Mar. 2nd, 1906.	"Improved."	A neighbour tells me that the child went abroad with parents 3 years after operation; talked indistinctly, but could be understood.		June, 1912.
54	F., 5 wks.	Complete; right harelip.	1. Mar. 6th, 1906. 2. Mar. 13th, 1906 (lip only). 3. May 15th, 1906 (lip only).	Healed. Failed.	Healed; both hard and soft palates much scarred. Arch of hard palate almost non-existent. Soft palate moves very little; uvula to left side. Alveolar arch and teeth irregular.	Nasal, but fair; usually intelligible; trouble especially with <i>s</i> and <i>r</i> .	Seen June, 1912.
55	M., 9 yrs.	Soft palate and part of hard.	1. Mar. 9th, 1906. 2. June 8th, 1906.	Failed.	Widely cleft.	Fair since insertion of obturator; before this unintelligible.	Letter from patient's dentist Nov., 1911.
56	F., 4 mos.	Soft palate.	Mar. 13th, 1906.	Not stated.	"The operation was a failure."	"She speaks very well and can be understood by strangers. She has not had any special training."	Letter from father Nov., 1911.
57	M., 2 wks.	Complete; no harelip.	1. Mar. 16th, 1906. 2. Nov. 2nd, 1906.	? Partial sloughing of flaps. Complete closure.	Healed; arch low. Soft palate short and almost immovable. Teeth slightly irregular in front; one premolar on each side badly carious.	Markedly nasal, but quite intelligible as a rule; trouble especially with <i>th</i> and <i>s</i> .	Seen Nov., 1911.
58	F., 2 wks.	Complete; left harelip.	Mar. 23rd, 1906.	—	Died a week after operation from pneumonia.		—
59	F., 7 yrs.	Soft, and posterior three-quarters of hard palate.	April 6th, 1906.	Complete closure.	Healed, with a good deal of scarring of hard palate. Soft palate very short, especially on left side. Moves moderately. Upper teeth in good condition, but extremely irregular. Lower teeth not irregular. (Fig. 2.)	Bad, and very nasal. Can be understood with difficulty; but is mentally dull.	Seen Dec., 1914.
60	M., 10 wks.	Soft, and small part of hard palate.	April 6th, 1906.	Held well.	Child very ill after operation with vomiting. Death 5½ weeks after operation, vomiting continuing.		Letter from father Nov., 1911.
61	F., 3 mos.	Soft, and small part of hard palate.	April 24th, 1906.	Held well.	Hard palate healed. Soft palate widely and irregularly cleft in almost its whole extent. Right half moves, but left half scarcely at all. Teeth natural.	Fair; distinctly nasal, but quite intelligible, especially as regards individual words.	Seen Nov., 1911.
62	F., 1½ yrs.	Soft, and posterior two-thirds of hard palate.	May 8th, 1906.	Small hole at anterior part.	Cannot be traced.		—
63	F., 10 wks.	Soft palate.	May 11th, 1906.	Partial closure.	Soft palate very short, apparently only the anterior part remaining, with a small portion and the remains of the uvula on the right side. Moves very little.	Fair, and said to be improving; nasal. Individual words easily intelligible, but continuous conversation not easily understood.	Seen Dec., 1911.
64	F., 6 wks.	Soft, and posterior two-thirds of hard palate.	May 22nd, 1906.	Healed.	Child died about three months after the operation, wasting all the while and going downhill after return from hospital.		Conversation with woman who nursed child in its illness, and letter from mother Feb., 1912.
65	M., 6 mos.	Complete; left harelip.	1. July 27th, 1906 2. Nov. 30th, 1906 3. June 14th, 1907 4. Aug., 1907 5. Feb., 1908.	Pneumonia after last operation, but recovered.	Hard palate healed, with lumpy scarring. Soft palate short, thick, nearly immovable. Only three teeth present in upper jaw, and those carious; lower teeth also bad. (Fig. 9)	Very bad; unintelligible.	Seen Dec., 1914.

TABLE III.—100 Consecutive Cases of Cleft Palate treated by Arbutnot Lane's Operation, with their Immediate and Remote Results—(Continued).

No.	Sex and age.	Extent of cleft.	Operations.	Immediate result.	Ultimate result.		Last report.
					Palate, &c.	Speech.	
66	F., 4 mos.	Soft, and posterior half of hard palate.	1. May 25th, 1906. 2. May 29th, 1906.	Flaps had to be loosened because of trouble with breathing on table. Second operation followed by abscess and erysipelas of arm.	"Her palate has not quite healed up. Her top teeth are bad."	"She speaks fairly well; has had no special training."	Letter from father, Nov., 1912.
67	M., 10 wks.	Soft, and small part of hard palate.	3. Jan. 24th, 1907. May 25th, 1906.	Middle part held. Not stated.	Good movable soft palate, but rather short; uvula good. Hard palate healed except a small hole at posterior part to right of middle line. Teeth very bad.	Bad, mostly unintelligible. Rather dull child; has not yet started school.	Seen May, 1912.
68	M., 2 yrs.	Soft, and posterior quarter of hard palate.	May 29th, 1906.	Slightly broke down.	Hard palate much scarred; healed except small hole towards left side. Soft palate short, and moves little. Uvula well marked—displaced to right.	Poor; individual words mostly intelligible, but markedly nasal; sentences only with difficulty intelligible; special difficulty with <i>p, w, br, s, z</i> .	Seen Dec., 1911.
69	M., 10 mos.	Complete; no harelip.	June 1st, 1906.	Healed.	Healed. Soft palate short, and moves only moderately. Several teeth displaced inwards. (Fig. 5.)	Fair; quite intelligible, but nasal. No special training, but parents always correct him; intelligent boy.	Seen Dec., 1911.
70	F., 1 yr.	Soft, and posterior three-quarters of hard palate.	June 8th, 1906.	Middle part healed.	Cannot be traced.		—
71	F., 2 mos.	Complete; right harelip.	1. June 12th, 1906. 2. Nov. 2nd, 1906 (lip only). 3. May 11th, 1907.	Partial closure. —	"The palate has given way a little and sometimes her food comes down her nose; her teeth are very bad."	"We can understand what she says, but a stranger would not."	Letter from father Nov., 1911.
72	F., 7 mos.	Soft, and posterior three-quarters of hard palate.	1. June 19th, 1906. 2. Oct. 8th, 1906.	Very ill with sepsis afterwards and part of palate gave way.	Healed; no arch. Soft palate short, scarred, and only slightly movable; posterior border oblique. Uvula long. Teeth very irregular; lateral incisors and 1st premolars lie on hard palate.	Good; only slightly nasal; trouble with <i>th, sh, and l</i> .	Seen Jan., 1912.
73	M., 13 mos.	Soft, and posterior two-thirds of hard palate.	1. June 19th, 1906. 2. Dec. 1st, 1910.	Slight gap left posteriorly.	Hard palate much scarred; healed except hole on left side opposite 2nd premolar. Soft palate short, and very little movable; posterior border very oblique, making palate very short on left side. Teeth in both jaws bad. (Fig. 4.)	Poor; only with difficulty intelligible. Only at school 3 months; improving much since then.	Seen Dec., 1911.
74	F., 4½ yrs.	Complete; left harelip cured.	July 6th, 1906.	Hæmorrhage after operation, necessitating anæsthetic and plugging posterior palatine canal with wax. Flaps held.	Cannot be traced.		—
75	F., 13 wks.	Complete; double incomplete harelip.	1. June 29th, 1906. 2. Nov. 27th, 1906. 3. July 5th, 1907.	"Flaps in main held." Hard palate healed. "Slight posterior deficiency."	"The palate is quite healed. Condition of top teeth very irregular and decayed."	"Speech very plain; no special training."	Letter from mother, Dec., 1911.
76	M., 3 wks.	Complete; left harelip.	1. June 29th, 1906. 2. Aug., 1906. 5. Nov. 21st, 1906. 4. Nov. 22nd, 1906 (readjustment of flaps). 5. Summer of 1908.	Hæmorrhage after operation. Flaps separated to stop bleeding.	Hard palate healed with much lumpy scarring; arch obliterated. Soft palate; only a narrow strip in front has healed; rest still cleft; the remnants move fairly well. (Fig. 8.)	Bad; unintelligible and very nasal; no special training.	Seen Jan., 1915.
77	F., 11 mos.	Soft, and posterior third of hard palate.	1. July 10th, 1906. 2. Nov. 13th, 1906. 3. Jan. 27th, 1907. 4. May 28th, 1907 (for hole in hard palate). 5. July, 1911.	Failure. Middle part held. Healed. Failure.	Much scarred; hard palate has no arch, and shows a large perforation anteriorly. Soft palate, short; small hole at middle; is moderately movable.	Poor; ordinary speech very nasal, and only intelligible with difficulty; individual words much better; special trouble with <i>t, f, th, and g</i> .	Seen Dec., 1911.
78	F., 11 days.	Soft, and posterior third of hard palate.	July 10th, 1906.	Failure. Much respiratory distress after operation.	Child died at home 3 weeks after operation.		Conversation with mother, June, 1912.
79	F., 9 days.	Complete; double harelip.	July 17th, 1906.	Not stated.	Death, Sept. 24th, 1906. After operation seemed worse than before; wasting, and finally diarrhoea and convulsions.		Conversation with mother, Dec., 1911.
80	M., 14 mos.	Complete; left harelip cured.	July 20th, 1906.	Not stated.	Healed; soft palate fairly good and movable, but posterior border is irregular.	Good; trouble with <i>s</i> and <i>sc</i> . Has been at school one year, and has improved very much.	Seen Dec., 1911.
81	F., 2½ yrs.	Soft, and most of hard palate.	1. July 24th, 1906. 2. Oct. 12th, 1906. 3. Dec. 14th, 1906. 4. May 14th, 1907. 5. Jan. 7th, 1908.	Anterior part not closed. Partial closure. — — —	"The palate is completely healed."	"She speaks with a nasal twang, but can be fairly well understood by strangers. She has had no special lessons in speaking."	Letter from father, Dec., 1911.
82	F., 4 mos.	Soft palate, and hard up to anterior palatine foramen; double harelip.	1. July 24th, 1906. 2. Nov. 2nd, 1906.	Failure. Not stated.	Child died at home 2 or 3 months after second operation.		Conversation with next door neighbour, June, 1912.

TABLE III.—100 Consecutive Cases of Cleft Palate Treated by Arbuthnot Lane's Operation, with their Immediate and Remote Results—(Continued).

No.	Sex and age.	Extent of cleft.	Operations.	Immediate result.	Ultimate result.		Last report.
					Palate, &c.	Speech.	
83	M., 5 mos.	Complete; double harelip.	Aug. 1st, 1906.	—	Diarrhoea and double otitis media after operation. Died Aug. 10th.		—
84	M., 3 mos.	Complete; left harelip.	1. Oct., 1906. 2. Dec., 1911 (palate and lip).	Chicken-pox after second operation.	Healed. Hard palate scarred; no arch. Soft palate very short on left side; fairly movable. Teeth rather irregular, otherwise fair.	Poor; nasal but generally intelligible with some trouble. At school irregularly for 3 months; speech said not to be improving.	Seen June, 1912.
85	M., 2 mos.	Complete; left harelip.	Oct. 5th, 1906.	—	Death at age of 4 months from pneumonia.		—
86	M., 5 days.	Soft, and hard up to anterior palatine foramen; left harelip.	1. Oct. 12th, 1906. 2. Jan. 8th, 1907. 3. June 25th, 1907. 4. Nov. 19th, 1907 (lip only). 5. ? date. 6. July, 1911.	— — — — — —	Hard palate healed, with much lumpy scarring. Soft palate much scarred, especially on left side; moves little. Small perforation on right side. Teeth fair; several have been removed.	Bad; very often unintelligible, even by parents.	Seen Dec., 1911.
87	F., 2 yrs.	Soft, and posterior two-thirds of hard palate.	1. Oct. 16th, 1906. 2. Jan. 15th, 1907. 3. Nov. 1st, 1907.	— — —	Healed, except for small perforation at posterior part of hard palate. Much scarring of both hard and soft palates. Soft palate very short, and immovable.	Poor; very nasal, and often only with difficulty intelligible.	Seen Oct., 1912.
88	F., 6 mos.	Complete; double harelip.	Oct. 23rd, 1906.	Not stated.	Death "in a fit through teething" when 15 months old.		Letter from father Dec., 1911.
89	M., 2½ yrs.	Cleft palate and harelip; the latter cured.	Oct. 25th, 1906 (soft palate only).	Not stated.	"Completely healed."	Speaks quite plainly, and anyone understands him as long as he speaks slowly.	Letter from father Dec., 1911.
90	F., 5 wks.	Complete; left harelip.	Oct. 30th, 1906.	Not stated.	Child died 3 weeks after operation; inability to suck and regurgitation of milk through nose persisted after operation. Death from broncho-pneumonia Nov. 11th.		Conversation with mother June, 1912.
91	M., 4 mos.	Soft palate, and hard as far as anterior palatine foramen.	Nov. 2nd, 1906.	Difficulty in breathing after operation; tracheotomy on Nov. 5th.	Child died from pneumonia a year after third operation; was to have had another operation.		Letters from father Dec., 1911.
92	F., 7 days.	Complete; left harelip.	1. Nov. 7th, 1906. 2. Jan. 29th, 1907. 3. June, 1907 (lip only).	A small part healed. Partial closure.	Child died when 3½ months old.		Letter from father Dec., 1911.
93	F., 5 wks.	Cleft palate and double harelip.	Oct. 21st, 1906.	Failure.	"He died under his third operation on May 1st, 1908, at the age of 18 months."		Letter from father Dec., 1911.
94	M., 7 wks.	Cleft palate and harelip.	1. Dec. 7th, 1906. 2. May 14th, 1907. 3. May 1st, 1908.	Partial closure. Partial closure. Not stated.	"Completely healed."		Letter from father Dec., 1911.
95	F., 10 wks.	Soft palate.	1. Dec. 11th, 1906. 2. May 17th, 1907.	Failure. "Did not entirely hold."	"She speaks very well; there are a few words she cannot quite pronounce."		Letter from father Dec., 1911.
96	F., 8 mos.	Soft, and small part of hard palate.	Dec. 11th, 1906.	Not stated.	Healed; uvula and soft palate good and movable. (Fig. 7.)	Very good; no nasal tone. Can pronounce all words with scarcely any defect.	Seen Dec., 1914.
97	M., 1 day.	Complete; double harelip.	1. Dec. 16th, 1906. 2. Feb. 5th, 1907.	Partial closure.	Death on Feb. 6th, 1907, from "marasmus and syncope."		—
98	F., 3 wks.	Soft, and posterior two-thirds of hard palate; congenital syphilis.	Jan. 22nd, 1907.	—	Death on Jan. 25th from "marasmus."		—
99	M., 4 mos.	Soft, and part of hard palate.	1. Jan. 8th, 1907. 2. ? date.	"Improved."	Healed; soft palate is short, rather tight, and moves very little; posterior border slightly oblique; uvula absent. Both upper and lower teeth very bad.	Poor; continuous conversation generally unintelligible; individual words fairly pronounced; intelligent child.	Seen Feb., 1912.
100	F., 7 wks.	Complete; right harelip.	Jan. 11th, 1907.	Bridge at back of hard palate healed.	"The baby died soon after going home."		—

Note.—All the cases in this series are "primary" cases—i.e., cases which had undergone no operation upon the palate previous to the first operation recorded here.

The statement of the age of the patient refers to the age at the time of the first operation.

uvula, is well formed. The boy speaks so well that one could not detect from his speech that he had any abnormality.

Another good result, in the case of a cleft of the soft and a part of the hard palate operated on at 8 months old (Case 96), is seen in Fig. 7. The patient's speech at the age of 9 is almost perfect.

The next drawing (Fig. 8) shows the palate of a boy, aged 8 (Case 76), upon whom five operations were performed for complete cleft palate; recurrent hæmorrhage occurred after the third operation. The hard palate is much scarred, the soft for the most part still not healed, and the speech is generally unintelligible.

Another case of an originally complete cleft is shown in Fig. 9 (Case 65). Five operations had been performed, the

first at 6 months old; the whole palate is much scarred, and the boy speaks very badly.

It cannot be said that these results afford support to the view that very early operation is necessary in order to secure good speech. Taking the cases of complete cleft as an example, the single case (No. 80) who spoke well five years after the operation was 14 months old when operated on, while none of the 11 cases whose speech was poor or bad were older than 6 months at the time of the first operation. The five cases of less severity whose speech was good (Cases 1, 8, 17, 72, and 96) were all more than six months of age when treated.

BROPHY'S OPERATION.

Views of its Advocates.

The third method of operation which needs detailed discussion is that devised by Brophy, of Chicago.²⁵ The theory upon which it is based is by now well known. It assumes the deformity to be due to failure of union between the two halves of the palate; each of these, however, is fully developed. When failure of union has occurred the two halves are separated from one another by the upward pressure of the mandible and of the tongue. As a result of this separation the upper jaw is found wider than it should be by the width of the cleft. It is evident that if this is so and the two halves of the upper jaw can be pushed together again and healing be secured, not only will the cleft in the palate be closed, but the jaws will be restored to their normal relationships, and moreover a loose and freely mobile soft palate, in which the element of tension has been abolished, will result, with corresponding improvement in the speech.

These are Brophy's claims, and in accordance with his views he has devised his operation of pushing the bones together in early infancy, and holding them in place by silver wires which transfix their substance and are twisted together over leaden plates applied to the outer side of the alveolar arch. This idea had been suggested by Reeves²⁶ in 1861, but the operation was not performed by him during life. I have not been able to obtain Reeves's paper.

The whole theory seems to depend upon the statement that the upper jaw "is just as much broader than it should be as the distance between the borders of the fissure." What is the standard to which the breadth of the upper jaw should conform? Brophy assumes in his writings that it should be equal to the breadth of the mandible, but advances little evidence in proof of this; as a matter of fact, it is the rule in normal infants to find the upper jaw wider than the lower, as is shown in this photograph (Fig. 10) of a coronal section through the head of a normal full-term foetus, cutting through the posterior part of the hard palate; the width of the upper jaw is 35 mm. while that of the lower is 31.

Table IV. gives the measurements of the width in millimetres of the upper and lower jaws of a series of normal, full-term foetuses. The average difference in favour of the upper jaw is 2.8 mm.

TABLE IV.—Width of Upper and Lower Jaws in a Series of Normal, Full-term Foetuses.

No.	Width of upper jaw.	Width of lower jaw.	No.	Width of upper jaw.	Width of lower jaw.
1 ...	31.5 mm.	30.5 mm.	9 ...	30.0 mm.	30.0 mm.
2 ...	36.5 "	31.5 "	10 ...	35.5 "	32.5 "
3 ...	30.0 "	30.0 "	11 ...	35.0 "	30.0 "

Birth ...	40.5 "	9.0 "	32.5 "
7 weeks ...	39.0 "	10.5 "	34.0 "

Table V. gives corresponding measurements of the jaws of 10 infants with complete cleft palate, with the width of the cleft in each case. Here the average difference in favour of the cleft upper jaw is greater than in the normal infants—8.05 mm.; but the average width of the cleft is 11.2 mm. A study both of the average and of the individual cases suggests that, while in cases of cleft palate the upper jaw is wider than the lower compared with the normal, the difference does not, as a rule, account for the width of the cleft; and the wider the cleft the less in proportion is it accounted for by mere pushing outwards of its two sides. Fig. 11 shows one of the cases in which the correspondence was exact, 4 mm. representing the extent both of the cleft and of the difference in width of the jaws.

Examination of skulls showing the condition makes it clear that in cleft palate there is a true defect or absence of tissue. The defect can be seen, and does not need to be inferred from such indirect evidence as that referred to above. The specimens which are before you show it very well, and it is particularly obvious in the case of a cleft involving only a half of the hard palate, in which the normal anterior part of the palate gives the measure of the tissue which should be present posteriorly.

In spite of the fact that this absence of tissue is well marked in the newly born, it has been suggested that it is the result of a secondary atrophy of the palatal processes, occurring after the bones have been pushed asunder. How, then, should the advocates of the theory contend that the width of the cleft is equal to the extent of separation of the maxillæ?

I do not doubt that the principle upon which Brophy's operation is based is unsound; but there can equally be little doubt that when the cleft condition is in existence the fissure is often further widened by the pressing asunder of the maxillæ, either by the pressure of the mandible or by the tongue—not improbably by both. The tongue normally, during early embryonic life, lies between the two palatal processes, as is well shown by Fig. 12, which represents a coronal section of the head of a human embryo of 8 weeks; and in a newly born infant with complete cleft palate the cleft is demonstrably widened by pushing the lower jaw firmly into contact with the upper. The same conclusion is suggested by the measurements already given, and by the oblique position of the pterygoid processes which is often seen in skulls presenting the condition. These processes in the normal skull are nearly vertical, but in cases of cleft palate their lower ends appear to have moved outwards with the maxillæ and palate bones.

It is evident from these considerations that it is not likely that, in most cases, actual closure of a cleft will be accomplished by approximation of the upper jaws, and that such closure will be generally undesirable on account of the narrowing of the jaw which would result.

Results.

In considering the published results of the operation it must be borne in mind that until 1911, when Dr. Brophy demonstrated it in London, the method has probably been imperfectly applied. Certainly his technique differed much from the accounts of it given in text-books at that time.

I shall summarise the results as I have seen them in 10 cases treated at St. Bartholomew's Hospital in 1911 and 1912 at ages varying from 3 weeks to 4 months. The details of these cases were communicated to the International Dental

FIG. 1.

FIG. 2.

FIG. 3.

FIG. 4.

Boy aged 10. (Case 4.) Condition 9½ years after operation for complete cleft. Palate completely healed, with scarring. The permanent teeth are healthy. Figs. 1 to 9 illustrate the results of operations by Lane's method.

Girl aged 15. (Case 59.) Condition 8 years after operation for cleft of the soft and most of the hard palate. Note the displacement of teeth produced by scarring.

Boy aged 12. (Case 29.) The palate, 9 years after operation for an incomplete cleft, shows scarring around a small hole, with resulting displacement of a bicuspid tooth.

Boy aged 6½. (Case 73.) Condition 5½ years after operation for a cleft of the soft and most of the hard palate. The palate is scarred and a small hole remains, towards which the left alveolar process is drawn in.

FIG. 5.

FIG. 6.

FIG. 7.

FIG. 8.

Boy aged 6. (Case 69.) Condition 5½ years after operation for complete cleft. The soft palate is short and the hard scarred, with displacement inwards of several teeth.

Boy aged 10. (Case 8.) Seen 9½ years after operation for cleft of the soft palate. The palate is well formed and movable, scarring is absent, and speech perfect.

Girl aged 9. (Case 96.) Condition 8 years after operation for an incomplete cleft. There is a good soft palate, and the patient speaks very well.

Boy aged 8½. (Case 76.) Had undergone five operations for complete cleft palate between the ages of 3 weeks and 2 years. The hard palate is much scarred, and the soft for the most part still cleft. The speech is bad.

FIG. 9.

FIG. 10.

FIG. 11.

Boy aged 9. (Case 65.) Condition 8½ years after first operation for complete cleft. No temporary teeth remain. The palate is much scarred, the soft palate stiff, and the speech bad.

A coronal section of the head of a full-term fetus, through the posterior part of the hard palate; to illustrate the fact that the upper jaw is normally wider than the lower.

A coronal section through the head of an anencephalic fetus, born at full term with cleft palate. The cleft is 4 mm. wide and the upper jaw is wider than the lower by 4 mm.

Congress last year. There were no deaths attributable to the operation, though 3 of the children have died from other causes.

The effect upon the cleft was disappointing and might have been attributed to lack of experience in the operation had not one of the cases, operated upon by Dr. Brophy himself, given similar results. In no case was closure of any part of the cleft

FIG. 12.

A section through the head of a human embryo of 8 weeks. The tongue is seen lying between the two halves of the palate, which are still separated by a wide gap.

effected, except of the gap in the alveolar arch, and possibly a small portion of the hard palate immediately behind this. In only one case was any considerable narrowing of the cleft brought about, and then only by the use of so much force that a fracture of one of the alveolar processes resulted.

These casts illustrate the result of an operation performed by Dr. Brophy (Fig. 13) upon a child 4 months old. The first cast shows the complete left-sided cleft (associated with left harelip) as it existed before the operation. As is usual in such cases the left nostril was large and flattened, and the nose deflected to the right side by the displacement of the premaxilla forwards and to the right. At the end of the operation the alveolar arch and the most anterior part of the hard palate had been closed, while the remainder of the cleft was somewhat narrowed. The effect upon the face was seen in the return of the nose to the middle line, in diminution of the width of the cleft in the lip, and in very great improvement in the shape of the nostril. Two days later only the alveolar arch remained joined, the rest of the cleft appearing almost as before. The second cast shows the condition six weeks later, when the plates and wires had been removed.

Through the courtesy of the authorities at the Hospital for Sick Children, Great Ormond-street, I had the opportunity of seeing a child who had been treated there by Dr. Brophy, when 6 days old, for complete cleft palate with right-sided harelip. The condition of the palate 10 weeks after the operation is seen in Fig. 14. Again only the alveolar arch has been closed, and, although I have no record of the width of the cleft previous to operation, it seems unlikely that any great narrowing had occurred.

None of the cases in the series had better results than these. Although I have not myself performed

Brophy's operation during life, I convinced myself by doing it after death in a case of double cleft palate and harelip, a cast of which is seen in this photograph (Fig. 15), that to approximate the opposite palatal processes, as long as the premaxillary bones remained in position, would have been impossible by any means short of fracturing the bones. The same conclusion was arrived at in the case of a child aged 3 months with double harelip and cleft palate. The condition before and after operation is seen in these casts. (Fig. 16.) When the two sides of the cleft had been approximated as much as was possible a gap of nearly half an inch still remained, although the upper and lower jaws were now equal in breadth.

No report can at present be made upon the speech of these patients, partly because they are still too young, and also because none of the seven survivors yet has the palate completely closed. Dr. Brophy showed, at the Clinical Congress of American Surgeons in July last, three patients all of whom spoke perfectly. Not all of these were examples of what can be achieved by his operation upon the bones in early infancy, one of the patients having been treated by Langenbeck's operation (without lateral incisions) in adolescence.

Much the most complete account of the early results of Brophy's operation has been given by Kaerger,²⁷ who is a warm advocate of the method. His report is based upon 54 cases, all, unfortunately, too recent for an account of the speech to be given. In cases of complete cleft palate with harelip he prefers to operate on the jaws by Brophy's method at about the age of 3 weeks. In cases of double harelip and cleft palate he not only wires the maxillæ themselves, but pushes the premaxilla back into place and fixes it there; he does not attempt to obtain union of the hard palate behind the premaxillæ by this operation. In complete unilateral clefts he usually expects to obtain union of the alveolar arch and of the anterior third of the hard palate, but has seen cases in which the whole hard palate was united. The shock of the operation is said to be so little that the children are often treated as out-patients. Kaerger usually closes the palate by median suture at the age of about 3 months, and operates on the harelip a fortnight later. He aims, therefore, at completing the treatment by the age of 3-4 months. Thirty-nine of the 54 cases had the plastic operation upon the bones performed; 3 deaths appear to have been due to this operation, while 3 others followed median suture of the palate, and 1 was due to operation for harelip. Of 18 cases of complete cleft in which the treatment had been completed, 13 are reported to have required only one operation for median suture of the palate.

OTHER METHODS INVOLVING PLASTIC OPERATIONS UPON THE BONES.

For the closure of clefts of the hard palate plastic operations upon the bones have at various times been used, since Dieffenbach in 1834 suggested making an incision through the mucous membrane at the side of the hard palate, dividing the palatal process longitudinally with a saw, and drawing the edges of the cleft together with wire sutures. Although he described the operation in detail in 1845 it is not known that he ever actually employed it. It was tried on the Continent by a number of surgeons, and in this country by Fergusson, but for the most part with indifferent success, and it has long been given up.

Gay²⁸ in 1851 bridged a cleft of the hard palate by turning down the septum nasi, already attached

along one side of the cleft. Weber described in 1859 an operation allied to Brophy's. His patient was a child, aged 6 weeks, the subject of right harelip and a cleft of the alveolar process as far as the anterior palatine foramen. The edges of the cleft were pared, and brought into contact by two wire sutures penetrating the bones. The result was good.³⁰

Schoemaker,³⁰ having been unsuccessful with Brophy's method, has modified it by mobilising the jaws so freely that all tension is abolished, and no special means are needed to keep the bones in place. At the same time he rotates the jaws on their antero-posterior axis, so as to make the palatal processes horizontal and to avoid as far as possible any narrowing of the upper jaw. His operation, which he advises for use on young infants, consists in chiselling through the maxilla from before backwards, just above the palatal process, on one or both sides; after the bones have been pushed together the edges are pared and sutured. He records 12 operations, with 1 death from hæmorrhage. The late results are not given. The operation appears to me to be entirely unjustifiable.

In older patients Helbing has tried to make wide clefts narrower before operation by the use of an apparatus which presses the jaws together. After this has been used for six weeks the molar teeth are nearer together by 2 cm., but the cleft is narrowed less than this because some rotation of the jaws on their antero-posterior axis occurs. He relates the case of a boy, aged 5½, upon whom an unsuccessful operation for a wide complete cleft had been performed at the age of 3. Helbing³¹ operated by dividing, on the right side, the junction of the maxilla with the malar, and then pushing the maxilla over towards the left side, where it was fixed with wires and plates. Paring and suture of the palate were done four days later. Complete healing followed, with no deformity. Codivilla³² describes a similar mode of treatment, successfully performed upon a boy, aged 5.

I saw in 1912 a boy, aged 5, who had a complete cleft palate which had been unsuccessfully operated upon, and which was judged to be too wide to be closed in the ordinary way. The patient was under the care of Mr. Waring. An incision was made in each cheek, and through these cuts an osteotome was introduced so as to separate the malar bone from the maxilla on each side. After the wounds had healed the maxillæ were approximated by a combination of pressure by an apparatus specially devised, and forcible movement under an anæsthetic. The cleft was in this way somewhat narrowed, and Langenbeck's operation was then performed with success. Some such method may have a limited field of application in cases otherwise inoperable.

CHOICE OF METHOD OF OPERATION.

I have not attempted to put before you any new suggestions as to the treatment of cleft palate, or even to advance anatomical or embryological data upon which new methods might be based. A more urgent need is a knowledge of the results which may be obtained by the existing methods of treatment. Such knowledge has in the past been available only in the case of Langenbeck's operation; I have tried to determine the results of Lane's and of Brophy's operations as well. Incomplete as the investigation is, it nevertheless affords material for a decision as to the choice of a routine method of operation.

I have said that the principle of Brophy's operation is unsound; but it is not clear that on that

account it ought to be altogether abandoned. It has this much of truth in it, that a cleft palate having developed, the cleft may be widened by separation of the two halves of the upper jaw; and there may be cases in which an operation by another method may be made easier and more likely to succeed by a preliminary approximation of the maxillæ, preferably during the first three months of life. The usual result of the operation

FIG. 13.

FIG. 16.

FIG. 13.—Photographs of casts illustrating the condition before and six weeks after Brophy's operation in a female child 4 months old. Closure of the alveolar arch has been effected, but the cleft of the palate is not greatly narrowed. Operation by Dr. Brophy. (Note that the nasal septum attached to the right side of the palate is very broad and fills a large part of the cleft.)

FIG. 14.—The palate of a child 10 weeks old, who had been operated upon by Dr. Brophy at the age of 6 days. Closure of the alveolar arch only has resulted from the operation.

FIG. 15.—A cast showing double cleft palate in an infant a few days old. The palatal processes are very deficient and their approximation by Brophy's operation was impossible.

FIG. 16.—Casts showing condition before and six weeks after Brophy's operation in a case of double cleft palate in an infant aged 3 months. The alveolar arch was closed, and the cleft behind this somewhat narrowed.

appears to be, however, closure only of the alveolar arch, with no great narrowing of the cleft behind this. Not inconsiderable, however, is the improvement in the appearance of the face produced by the bringing of the nose to the mid-line and the narrowing of the cleft in the lip. Granted that the mortality of the method is probably not high, is it justifiable to recommend it as a routine measure to obtain such a result? Each surgeon will decide for himself, but the matter is at any rate doubtful, especially as it is well known that almost similar

results may follow, with much less risk, if the harelip be closed and an interval of a few months be allowed to elapse.

And, with reference to the possible bad cases of cleft palate in which Brophy's operation might be used as a preliminary to other methods of treatment, such cases can probably all be closed either by Lane's operation in early infancy or by Langenbeck's method at a later date. But since more than mere closure of the cleft is aimed at, it is likely that the ultimate functional result will sometimes be better if Brophy's operation has been carried out as a preliminary. As a routine measure I think that it ought not to be used.

The rival claims of the operation of median suture and of that of the turn-over flap will continue to be discussed. Surgeons accustomed to use one of these methods with success (and success may be obtained by either) will not readily abandon it for the other. My personal belief is that in cases of cleft of the soft palate alone, or of the soft palate and a small part of the hard, there is probably little to choose between the results in cases treated by the best hands; but that in cases of greater severity there is a much better prospect of success if Langenbeck's operation is used at a suitable age by a surgeon accustomed to its performance.

It can no longer be urged in favour of the flap operation either that it is a life-saving measure or that very early operation is likely to result in greatly improved speech. The facts that I have laid before you suggest the contrary.

I conclude that Langenbeck's operation is still the best for routine use. The question as to the best age for its performance does not admit of precise answer. It is doubtful if any great advantage results from performing it during the first year of life, and it is certain that the prospect of success during the second or third year will often be better. Further delay is not usually necessary, but may in bad cases be advisable. Surgeons who a few years ago were content to operate in the third year or later now often perform median suture on children 1 or 2 years old. The experience of the operator, the width of the cleft, together with the height of the palatal arch and the general health of the child, have all to be considered before a decision is reached. If the condition is complicated by the presence of a harelip closure of the latter during the first few weeks of life has a valuable effect in causing obliteration of the most anterior part of the cleft.

AN OUTBREAK OF TOXIC JAUNDICE DUE TO TETRACHLOR- ETHANE POISONING.

A NEW TYPE AMONGST AEROPLANE WORKERS.¹

By WILLIAM HENRY WILLCOX, M.D., B.Sc. LOND.,
F.R.C.P. LOND., F.I.C., D.P.H., &c.,

PHYSICIAN TO ST. MARY'S HOSPITAL; SENIOR SCIENTIFIC ANALYST
TO THE HOME OFFICE, ENGLAND.

In September and October of 1914 the occurrence of several cases of illness associated with jaundice was noticed at the Hendon Aeroplane Factory. Cases of a similar nature were later observed at other aeroplane and seaplane factories. The outbreak of war naturally caused greatly increased activity in these factories, and the workers were employed overtime, so that any toxic influences to which they might be exposed in their work would be greatly increased.

My first acquaintance with the subject of my paper was on Nov. 5th, 1914, at my out-patient department at St. Mary's Hospital. The case was as follows.

CASE 1.—The patient was a man aged 36. The history of his case was that he had been employed at the Hendon Aeroplane Factory since August 8th. On Oct. 24th patient felt ill; he had nausea and retching in the morning, some slight pain in upper abdomen, and jaundice. He gave up work. His symptoms increased in severity. At my examination there was marked jaundice present; the patient appeared seriously ill. Pulse 96; temperature 99.5° F. Liver felt about 1 inch below right subcostal border in right nipple line on inspiration. No abdominal tenderness was present; no anæmia. Patient said the stools were pale and urine high-coloured. There was no history or evidence of syphilis or alcoholism. The tongue was furred and dry. Patient said he thought his illness was due to some condition associated with his work because ten other workers were affected similarly. On inquiry he stated that aeroplane "dope" was used in the factory, and he thought this was composed of "collodion, chloroform, ether, and acetone." He said that men who did not use the dope also suffered from the illness, but several of those who were using the dope had been taken ill. A diagnosis of toxic jaundice was made, and it was thought probable that some constituent of the dope was the cause of patient's illness. I did not see the patient again, but I heard that on Nov. 14th he was admitted to the Middlesex Hospital and died there on the 26th.

The case was referred to Mr. Luxmore Drew, H.M. coroner, and he after careful consideration decided that a post-mortem examination should be held. This was made by Dr. Spilsbury, who found a shrunken liver markedly bile-stained. Dr. T. M. Legge, Medical Inspector of Factories, Home Office, also investigated the case, and it was thought that the condition of the liver might be connected with the action of some poison to which the deceased was exposed during life.

A number of animal experiments were conducted by me relating to the possible toxic action of the constituents of the dopes used at the aeroplane factory, and it was clearly demonstrated that one of the constituents—viz., tetrachlorethane—was a powerful liver and kidney poison causing fatty degeneration of the cells of these organs.

Careful investigations were made by Dr. Legge and myself into the health of other employees at the factory and into the conditions of work there.

All the facts were carefully placed before the learned coroner, Mr. Luxmore Drew, who made a most careful and painstaking inquiry into the case, and as a result the jury found that death was due to degeneration of the liver caused by tetrachlorethane present in the cellulose varnish or dope used by deceased and to the vapours of which he was exposed during life.

¹ A paper read before the Medical Society of London on March 1st, 1915.

A number of other cases have been carefully examined by me, thus:—

CASE 2.—Male aged 48. Began work on August 10th, 1914; left work on Oct. 19th. He complained of constipation, sick headache, jaundice, nausea, and weakness, and some soreness of eyes. The urine was high-coloured; stools were pale. Patient returned to work on Nov. 9th, but gave up work again on the 23rd. On examination on Dec. 10th definite enlargement of liver was noticed; it was not tender. Slight jaundice was present but definite. Patient made a good recovery on being kept away from his work.

CASE 3.—Male aged 23. He commenced work on August 26th, 1914; gave up work on Nov. 30th. He complained of nausea, sickness in morning, and some slight pain in upper abdomen. He had been working near where doping was done. On examination on Dec. 3rd slight icterus was present; no anaemia; the liver was slightly enlarged; pulse 96. Patient made a good recovery on being kept away from his work.

CASE 4.—Male aged 53. He commenced work on August 31st, 1914; gave up work on Oct. 27th. He was weak and ill, with loss of appetite. He had dryness of throat. He was sick daily for 14 days. He was light-headed at night. He had definite jaundice, the urine being high-coloured and the stools pale. There was no abdominal pain. The liver was slightly enlarged. Slight but definite icterus was present; no anaemia. Patient made a good recovery.

CASE 5.—Male aged 44. He commenced work on August 22nd, 1914; gave up work on Nov. 30th. He complained of irritation of throat, loss of appetite, drowsiness, headache, and vomiting on two occasions before giving up work. Slight but definite jaundice was present on Dec. 10th. The liver was slightly enlarged; no tenderness over it. Patient made a good recovery.

CASE 6.—Male aged 47. He began work on Sept. 22nd, 1914; gave up work on Nov. 23rd. He did much overtime and used dope. He had loss of appetite, nausea, constipation, drowsiness, sickness in morning, and definite jaundice. The stools were pale and urine high coloured. On examination the liver was found slightly enlarged. Patient said he was a bilious subject. He made a good recovery.

CASE 7.—Male aged 28. He began work on August 13th, 1914; gave up work on Nov. 7th. He returned to work on Nov. 14th and gave up work again on the 21st. Patient had loss of appetite, nausea, vomiting at times, constipation, drowsiness at work, and dryness in throat. On examination definite jaundice was present. There was no abdominal tenderness. Slight enlargement of liver was present. Patient made a good recovery.

CASE 8.—Male aged 24. He commenced work on August 14th, 1914. He used the dope varnish. He very soon began to feel ill. He suffered from loss of appetite, nausea, constipation, headaches, and nasty taste in back of throat; was drowsy while at work; general weakness was complained of. He gave up work on Dec. 7th. On examination there was slight but definite jaundice. Temperature 99.2°F. The liver was somewhat enlarged, the lower border reaching three-quarters of an inch below right subcostal border in the right nipple line. There was no tenderness in abdomen. No signs of alcoholism or syphilis were present. He said the stools had been biscuit coloured. The patient made a good recovery.

CASE 9.—Male aged 49. He commenced work on Sept. 15th, 1914; at once began to feel ill. He suffered from drowsiness, constipation, and slight headache. The stools became pale in colour. There was no abdominal pain. Definite jaundice occurred on Oct. 7th, but cleared up before Nov. 2nd. He gave up work but resumed again on Nov. 2nd; the symptoms at once recurred. He now had sickness and the jaundice reappeared on Nov. 19th. He gave up work for the second time. The jaundice was now deeper than before, the stools were pale, and urine dark coloured. On examination on Dec. 17th there was still definite jaundice of slight depth. The liver was slightly enlarged, the lower border reaching half an inch below right subcostal border on inspiration. Patient improved slowly, but got well.

CASE 10.—Male aged 31. He commenced work on August 12th, 1914. He began to feel ill about Dec. 1st. He complained of loss of appetite, headache, peculiar taste

in mouth, drowsiness, nausea, and retching in morning. He was sick on Jan. 6th, 8th, and 9th, 1915. He became slightly jaundiced and gave up work on Jan. 9th. On examination on the 11th slight icterus was present. The liver was slightly enlarged, being felt about half an inch below subcostal border in right nipple line. Patient seemed in a marked toxic condition considering the slight amount of icterus present. He made a good recovery.

CASE 11.—Male aged 58. He began to work at Hendon on June 3rd, 1914. He was working close to where the dope was used. He left work on Sept. 21st. He was weak, felt drowsy, had no appetite, no energy, and the bowels were constipated. He had nausea, vomiting on one occasion. Jaundice developed on Sept. 14th. The patient became deeply jaundiced, with pale stools and high-coloured urine. He went to hospital on Oct. 2nd and was in there seven weeks. He developed ascites while in hospital and this increased. Edema of the legs also developed. The urine on examination by Dr. J. M. Bernstein showed a deposit of leucin. On Jan. 1st, 1915, paracentesis was performed by me and 22 pints of clear ascitic fluid were drawn off. The fluid gradually reaccumulated, and about three weeks later paracentesis was again performed by Dr. W. H. Ogle-Skan, who removed 21 pints of ascitic fluid. The fluid reaccumulated after this tapping, but Dr. Ogle-Skan tells me that absorption of the fluid has commenced and that patient is much improved in health and strength, and seems in a fair way to recovery. There was no history or evidence of alcoholism or syphilis in this case.

Other cases than those above described occurred at Hendon, but these are all on which a detailed clinical examination was made by me. In none of the above cases was there a history of alcoholic excess or of syphilis. In several of the cases the Wassermann test for syphilis was applied, but in every case the result was negative.

On Dec. 4th, 1914, I visited the Hendon aeroplane works. The smell of tetrachlorethane was very much in evidence, and at that time the ventilating arrangements by the plenum system were such that the heavy vapour of the dope was blown about the large room of the factory instead of being extracted. A reference to a plan on which were marked the places where affected persons worked showed that several cases of jaundice occurred at quite considerable distances—e.g., 30 or 40 yards—from where the dope varnishing was done. The more severe cases occurred in persons who were actually using the dope or were near where it was used. On questioning some of those working in the factory at the time of my visit I found that several workers complained of nausea, biliousness, drowsiness, constipation, loss of appetite, nasty taste at the back of the throat, headache, and general malaise, these symptoms being no doubt due to the dope vapour.

Cases of illness similar to those at Hendon have occurred in other factories where tetrachlorethane has been used. At the aeroplane factory at Crayford two severe cases occurred.

CASE 12.—Female aged 19. She commenced work in August, 1914. About Nov. 15th the patient complained of the smell of the dope, of discomfort in throat, and drowsiness. On Dec. 27th she became acutely ill with jaundice; there was vomiting and some abdominal pain. She became worse and on Jan. 2nd, 1915, vomited blood, was stuporose, and had convulsive twitchings. The stupor deepened into coma which lasted two days, when death supervened.

Necropsy.—The liver was hard and firm; it was very yellow and showed marked congestion; weight 34½ oz. The kidneys showed marked yellow staining of the cortex, the pyramids being intensely congested. The medulla was yellow and congested. The kidneys weighed each 5 oz. The heart weighed 7½ oz. The muscle showed yellow staining; some pink staining of endocardium. Numerous petechiae were present over surface of left ventricle. The small intestine showed intense petechial hæmorrhage over

the surface. There was marked congestion of the small intestine. The spleen weighed 8 oz.; it was hard and firm. Microscopical examination of the liver showed extensive necrosis, and in the kidney fatty degeneration was present.

CASE 13.—Female aged 17. She was working in the aeroplane factory for 4 months. On Jan. 14th, 1915, she felt ill; complained of discomfort in throat and general weakness. On the 28th she gave up work. She complained of nausea, sickness, and constipation. Jaundice occurred at this date. Patient was examined on Feb. 25th. There were intense jaundice, stupor, and delirium. The liver could not be felt. Spleen could not be felt. There was some dulness in flanks, which became resonant when patient rolled on to side. The urine contained much bile and a trace of albumin; many epithelial and granular casts were present. Patient became worse, passing into coma, and death occurred on Feb. 28th.

A fatal case occurred at the Seaplane Works, Rochester.

CASE 14.—Female aged 34. She commenced work in September, 1914. She worked overtime. On Dec. 7th she complained of feeling of illness and loss of appetite. On the 21st she gave up work. She was then jaundiced and complained of biliousness; she had abdominal discomfort, vomiting, and headache; constipation was present. On the 23rd she was dazed and confused; could not understand questions. On the 24th there was more severe abdominal pain and very deep jaundice. On the 25th she became drowsy, very little urine being passed. Delirium occurred on the 27th, and patient passed into coma, death occurring on Jan. 1st, 1915.

Necropsy.—The liver was shrunken; weight 20 oz. It was hard and firm. There was intense yellow staining. Gall-bladder was normal. The small intestine and mesentery showed marked congestion. The kidneys showed yellow staining of cortex and intense congestion of pyramids. Microscopical examination showed necrosis and degeneration of the liver cells, and fatty degeneration of the cells of the kidney.

Symptoms.

The following is a general résumé of the symptoms of tetrachlorethane poisoning. For some days the patients complain of general malaise, drowsiness while at work, loss of appetite, nausea, retching in the morning, unpleasant taste in the throat, constipation usually, and headache. Abdominal discomfort is present in some cases. After indefinite symptoms of this kind, lasting several days or even weeks, definite jaundice develops, and this is associated with pale stools and bilious urine. Vomiting is now likely to become more marked. The patient may become mentally confused, stuporose, or delirious. In acute cases hæmatemesis or convulsions may occur. Coma supervenes and death results. In the toxic stage of the disease purpuric rash and hæmorrhages may occur. Suppression of urine also occurs towards the end.

If the patient is removed from the influence of the poison in the early stages of the illness the symptoms clear up, but it is some weeks before the jaundice becomes completely free, even if it is only slightly marked. In cases with deep jaundice the prognosis is bad and recovery is unlikely. In one very interesting case (No. 11, Hendon Series) the patient recovered from the acute symptoms of a rather severe attack, but afterwards signs of contraction of the liver with portal obstruction developed, marked ascites resulting. It is interesting to record that after two operations of paracentesis the patient is making a good recovery.

In the early stages of the illness the liver appears to be slightly enlarged, no abdominal tenderness being present. Later the liver diminishes in size. The urine contains in the late stages of a severe

course much bile, a small amount of albumin and numerous casts, epithelial and granular casts predominating. No leucin and tyrosin crystals have been found by me in the unconcentrated urine, but as I have only had an opportunity of examining the urine in one acute case shortly before death I cannot speak as to the frequency of occurrence of leucin and tyrosin crystals. No acetone or diacetic acid has been found in the urines examined.

Interesting clinical features of the action of tetrachlorethane on the liver in the case of the aeroplane workers in this country are: (1) The insidious onset of the symptoms. (2) The comparatively long duration of the acute stage when marked jaundice has supervened, thus distinguishing the cases from acute yellow atrophy of the liver. (3) The absence of marked pyrexia, thus distinguishing the cases from infectious jaundice (Weil's disease). (4) The absence of anæmia, thus distinguishing the cases from poisoning by poisons which cause marked blood destruction—e.g., arseniuretted hydrogen, &c. (5) The marked depth of the jaundice, which is much deeper than is usually seen in cases of delayed chloroform poisoning.

There seems to be a marked variation in the susceptibility of certain persons to the poison, and this corresponds to the varying susceptibility of patients to other liver poisons—e.g., chloroform as described by Dr. L. G. Guthrie.

The jaundice appears to be of the toxæmic type, or hæmohepatogenous jaundice of Rolleston, and the exact type of the symptoms appears to be distinguishable from those of previously described liver poisons. There is no doubt that the question of dosage plays a very important part in the type of symptoms and in the incidence-rate of the illness. Thus the body is able to deal with very small amounts of the poison. When the quantity of poison absorbed becomes greater than the amount which can be dealt with, then symptoms result, and these will be progressive unless the patient is removed from the influence of the poison. The effect of increased dosage in causing illness is well shown by the effects of overtime and the increase in the quantity of dope varnish used in causing illness, whereas under previous conditions no harm resulted to the health of the workers.

It is interesting to record that on May 13th, 1914, a report was issued by Dr. Heffter and Dr. Kraus on Industrial Poisoning by Tetrachlorethane. In Germany the dope used contained a much higher percentage of tetrachlorethane than the English varnishes. As a result of this two types of symptoms resulted: (1) In one type of case gastro-intestinal and hepatic occurred as in the English cases; (2) in the other type of case nervous symptoms predominated, the patients suffering from tremors, headache, pains in limbs, numbness, pins and needles of extremities, loss of knee-jerks, and excessive sweating. In the German investigations some experiments on animals were carried out with a view to showing the anæsthetic action of the drug, but no post-mortem examination was made on the animals treated, and no direct proof was afforded of the poisonous action of tetrachlorethane on the liver.

Treatment.

Prevention of poisoning by the vapour of tetrachlorethane is of much greater importance than the treatment of patients suffering from this intoxication. Effective measures have been instituted in all factories where tetrachlorethane is used whereby

the heavy vapour is removed by powerful extraction fans, which remove the vapour at a low level and rapidly withdraw it from the workers. The Home Office have taken prompt action in the issuing of warning instructions, and in ensuring the provision of satisfactory measures for removal as far as possible of any danger to workers from the vapour of the dope used.

The treatment of patients suffering from toxic jaundice due to "dope vapour" consists firstly in their removal from all influence of the poison. Rest, light diet containing a much reduced amount of protein, saline aperients, and general hygienic measures are all that are necessary in mild cases. It is important that a patient should not be allowed to return to his work for a long period, at least a month elapsing after the jaundice has quite cleared up. Resumption of work should not be permitted unless the methods of removal of tetrachlorethane vapour in the factory where the patient is employed are effective.

Toxicological Aspects.

In considering the Hendon cases the first question that arose was, Were the symptoms due to some natural disease such as catarrhal jaundice, acute yellow atrophy, or jaundice of an infectious type; or were they due to some poison which had a special action on the liver? A careful review of the cases indicated that the symptoms were not consistent with natural disease, but were indicative of some poison acting on the liver.

The conditions obtaining at the aeroplane factories rendered it extremely probable that the "dope" vapour which contaminated the air to which the workers were exposed was responsible for the outbreak of illness. Also the conditions of work showed on investigating the individual cases that those workers who had been most exposed to dope vapour were most likely to suffer from illness, and speaking broadly the severity of the illness corresponded to the extent to which the patient had been exposed to dope vapour.

Dope or Cellulose Varnish.

This is a solution of acetate of cellulose in a mixture of benzene, acetone, methylated spirit, and tetrachlorethane. The proportions of the constituents vary with different types of varnish. The dope is a viscid, colourless liquid smelling something like chloroform. If applied to calico it forms on drying a firm, airtight and waterproof coating. Several coats of dope are given to the calico stretched on the framework of the aeroplane wings. The evaporation of the dope does not lead to a separation of its volatile constituents. A vapour comes off which appears to be a mixture of the volatile constituents of the dope. The vapour density of this was found to be 1.91 times that of air. If dope is distilled the bulk of the liquid distils over from 63° to 80° C., although the boiling point of tetrachlorethane is 147° C.

It is necessary for the drying to take place in a warm chamber. It appears that tetrachlorethane is a valuable constituent of the dope, since there is difficulty in getting such a good firm coating with a cellulose varnish in which tetrachlorethane is not present.

Experiments were instituted to test each of the constituents of the dope and the dope itself as regards the toxic action of their vapour on the liver.

For each experiment a large glass chamber (dessicator) was used. In the bottom of this were placed daily 10 c.c.

of the liquid to be tested. A perforated zinc platform was stretched across the middle of the chamber—i.e., half way up. On this were placed the animals to be experimented upon. The top of the chamber was covered with a perforated zinc roof. Rats were selected as the most suitable animals. The animals were kept in the glass chamber for eight hours a day for a week.

The liquids tested were dope, tetrachlorethane, acetone, benzene, and methylated spirit respectively. Two rats were placed in each chamber, five experiments being carried out together.

The rats thus exposed to dope vapour and tetrachlorethane vapour became very drowsy and slept all day. After removal from the chamber they remained drowsy for some little time, and on some occasions they were quite ataxic in gait, falling over on to their sides. After an hour or more usually they fed and became active. These animals did not gain in weight during the week's treatment.

In the experiments with acetone, benzene, and methylated spirit the animals were drowsy while exposed to the respective vapours, but on removal from it they immediately became lively and fed well. No ataxic symptoms were observed. All these animals gained markedly in weight during the week.

After seven days' treatment the animals were killed, and post-mortem examinations were made on them by Dr. Spilsbury and myself. The tetrachlorethane rats showed marked changes in the liver to the naked eye, there being fatty degeneration and bile-staining present. The "dope" rats showed similar changes but less marked. The rats exposed to the vapour of benzene, acetone, and methylated spirit showed no changes in the liver to the naked eye.

Careful microscopical examination of the organs showed marked fatty degeneration and cloudy swelling in the liver and kidneys of rats exposed to dope vapour and tetrachlorethane vapour, but no abnormal change in the animals exposed to the other vapours. Rats were also exposed to the action of dope vapour and tetrachlorethane vapour for five weeks. Marked diminution in size in the liver occurred in each case. The liver and kidneys were pale on section. They showed cloudy swelling and fatty degeneration.

The above experiments showed conclusively that tetrachlorethane is a powerful liver poison, and also they show that dope vapour is a liver poison, and that the poisonous property of dope vapour is due to tetrachlorethane being present in it.

In 1909 I made several experiments with tetrachlorethane on cats and rats in order to determine the anæsthetic effect of the drug. The vapour was found to be a powerful anæsthetic, but after removal from the vapour it was a long time before the animal recovered from the effects, sometimes 24 hours or more being required. It was obvious that tetrachlorethane was much more poisonous than chloroform as regards its anæsthetic effects.

About this time experiments were carried out by Dr. Veley, F.R.S., in the Physiological Laboratory of the University of London, and these showed that, weight for weight, tetrachlorethane was 2.8 times as powerful a tissue poison as chloroform.²

Tetrachlorethane is a colourless liquid,

Its boiling point is 147° and specific gravity 1.614. It has a smell like that of chloroform. It is not inflammable. It is known as acetylene tetrachloride and by the trade name of "cellon." It is used largely owing to its excellent solvent properties for resins, acetate of cellulose, &c.

There is no doubt that this compound is a powerful poison to the liver and kidneys, and that it is also a powerful narcotic poison. Every care should be taken in the use of tetrachlorethane to prevent as far as possible inhalation of the vapour.

Welbeck-street, W.

² Proceedings of the Royal Society, Series B, vol. lxxxii., 1910.

SURGICAL NOTES ON SERIOUS HEAD INJURIES.

(From an Evacuation Hospital, British Expeditionary Force, France.)

By A. G. WHITEHORNE-COLE, M.R.C.S. ENG.,
L.R.C.P. LOND.,MAJOR (TEMP.) R.A.M.C.; SENIOR STAFF SURGEON TO THE ALLIED
FORCES BASE HOSPITAL.

THE following cases may be of some surgical interest as illustrating the large amount of injury sustained by the bony skull and underlying brain tissues; also the enormous amount of brain injury and destruction which can take place, and yet the patient may recover to an almost normal condition of life and intelligence, and in a comparatively short space of time. In this hospital one has had the opportunity of seeing a very large number of head injuries, the results of rifle and shrapnel bullets, and the procedure which I invariably adopted was that of carrying out the minimum amount of surgical interference compatible with the injuries, and the undermentioned cases tend to illustrate that point. In those cases where the bullet was deeply lodged in the brain substance it was considered inadvisable to search for it, since the further laceration of the tissues engendered by the process would be more injurious to the patient than the foreign body itself. Before proceeding to operate the head was entirely shaved, under the anæsthetic, then thoroughly cleansed with ether soap, then washed with spirit, and finally painted with iodine. I noticed that all these cases took the anæsthetic remarkably well, never showing any bad after-effects—viz., sickness, &c. The anæsthetic usually employed was CHCl_3 or CHCl_3 and ether.

CASE 1.—Private, 2nd Dublin Fusiliers. Compound comminuted fracture of skull from shrapnel bullet; septic, large wound situate on vertex of the skull just behind the Rolandic area. On admission on Nov. 22nd, 1914, the patient was very bad, speechless; rapidly became worse and more and more comatose; pulse 48; temperature 99.8°F ., the breathing becoming stertorous; face swollen and puffy; no paralysis.

Operation shortly after admission. A large flap was turned down, when it was seen that the vertex of the skull for an area of about 5 to 6 inches was smashed in, being reduced to a number of small fragments, one of such being driven into and blocking the superior longitudinal sinus. The dura and underlying brain tissue were very considerably damaged. The fragmented bone was removed and the edges of the bone clipped away. The superior longitudinal sinus was plugged, the dura and lacerated brain attended to, scalp wound sutured and drain inserted. Iodine was then applied to the scalp and the wound dressed with gauze soaked in 1 in 40 carbolic.

Nov. 23rd: Patient very drowsy; pulse 80; temperature 100° ; answers when spoken to, but understands very little; face very swollen. 27th: Temperature 98° ; pulse 116; dressing quite clean. Plug removed from superior longitudinal sinus, which was quite sweet. Evening temperature 102° ; pulse 124. 28th: Temperature 102.2° ; pulse 120. 30th: Wound fairly clean; speaks and fully understands what is said to him, &c.—viz., mental condition normal. Temperature 99° ; pulse 104; face still swollen. Dec. 1st: Since operation both legs have gradually become paralysed and slightly rigid, with rather exaggerated knee-jerks. The right arm and hand have also gradually become paralysed, commencing from about the fourth day following the operation. Left arm normal. Incontinence of urine noted to-day. Temperature 99° ; pulse 112. 2nd: Patient able to open and shut right hand. Temperature normal; pulse 120. 8th: Wound moderately clean. Able to move right hand normally, but not arm; legs still paralysed; complains of cramp-like pains in both legs. 9th: Face much less swollen; wound progressing satisfactorily. Can move right arm very

slightly. Temperature 97.4° ; pulse 84. 10th: Patient able to move arm better, though very slightly. 13th: Wound satisfactory. The patient is able to move right arm almost normally; moves both legs very slightly for the first time; incontinence ceased. Temperature and pulse normal. 16th: Still slight movement of legs noticeable and much less pain, otherwise condition excellent; mental condition normal. 24th: Patient complains of no pain in his legs, and is able to move the left leg up and down very slowly, and only able to move the right leg down. General condition excellent. Evacuated to hospital ship.

CASE 2.—Private, 2nd Coldstream Guards. Compound comminuted fracture of the skull from rifle bullet, the entrance and exit wounds being about 4 inches apart. The entrance wound was situate slightly anterior to and below the parietal eminence of the left parietal bone, and the exit wound near the posterior superior angle of that bone; both wounds septic. The patient was aphasic on admission on Oct. 25th, 1914—in fact, the only word he could utter to anything that was asked him being "Yes"; also right hemiplegia.

Operation shortly after admission, when it was found that the greater portion of the left parietal bone, and the adjoining portions of the left occipital and frontal bones were fragmented. The dura and underlying brain tissue were considerably damaged. The parietal bone on the opposite side was loose. All the loose fragments and spicules of bone were removed; the dura and underlying damaged brain tissue were carefully attended to, all pressure being relieved. The scalp was sutured and the wound drained.

Oct. 26th: Patient looking well. Still could only utter the word "Yes." Was very sensible; evidently knew what was said to him, but could not answer; he apparently knew what the answer should be—aphasia. Hemiplegia; retention of urine, followed by incontinence. Towards evening he was dull and sleepy. Wound dressed with alcohol and looked very well; large amount of serous exudation. 29th: General condition much improved; patient much more alert. 31st: Wound still slightly septic, but healed in places. A small amount of brain substance was noticed bulging through the wound in the region of drainage. Treated with iodine and alcoholic dressings. Nov. 2nd: It was noticed that the patient on being asked questions would still answer "Yes," but was evidently aware that this was the wrong answer, since he promptly became irritable and slapped his chest. If the right answer was suggested to him he immediately became quiet and nodded his head with approval. 10th: Hernia cerebri practically disappeared; slight serous discharge; general condition good. Temperature and pulse normal; bladder symptoms disappeared. 13th: Slight movement noticed in the right lower limb. He is now able to speak a few words. Would frequently use the wrong word, but after some little thought would invariably be able to supply the correct word. The words are very slow and deliberate. Mental attitude happy and genial. 15th: General condition still improving; speech improving; can read the daily paper a little. Right lower limb is becoming much stronger; still slight discharge from wound. 17th: Wound clean, no discharge. Patient now began to move right arm slightly; movements of lower limb more pronounced; speech improving. 20th: Right arm movements are much stronger, and by placing the arm in a certain position on a pillow or support at his side he can flex it from the elbow. 24th: Wound healed. Movements of the right arm, hand, and fingers are much stronger, but that of the thumb is somewhat behind. He can now read, talk, and walk. Was evacuated to hospital ship.

CHCl_3 anæsthesia was administered, which the patient took remarkably well, and there was no after sickness. This was a very remarkable and interesting case to watch. From the day following the operation one noticed the intelligent look in his face on being questioned or on approaching his bed, although he could only utter one word, which after a short time he knew to be the wrong word; also to follow the various centres gradually resume their normal functions again.

CASE 3.—Private, Irish Guards. Compound comminuted fracture of the skull from rifle bullet. Admitted on Nov. 19th, 1914, in a semi-conscious condition, with an entrance and

exit wound. The entrance wound was situate at a point about the centre of the left eyebrow and about a quarter of an inch above, and the exit wound through the temporal muscle above the left ear. Marked œdema of both eyelids; left corneal hæmorrhage; left facial paralysis; no further paralysis. Temperature 101.4° F.; pulse 88; wound somewhat septic; very restless and irritable and in much pain.

Operation on Nov. 20th; anæsthetic, ether. A semicircular incision was made joining the entrance and exit wounds; flap turned down. It was found that the outer portion of the frontal bone and the orbital plate of that bone were fragmented, and a fissure extended through the temporal bone from the point of exit of the bullet down to the zygoma. All fragments of bone were removed, the temporal muscle was repaired, and the wound cleaned up and closed; a tube for drainage was inserted. Temperature 101°; pulse 76.

Nov. 21st: Temperature 103.4°; pulse 96. Wound looked fairly clean; one stitch was removed. 22nd: Temperature 102°; pulse 74. 23rd: Temperature 101.6°; pulse 78. Wound dressed; a small exudate of pus was noticed; tube removed. Wound flushed out with iodine solution; a gauze drain inserted. 24th: Temperature 100°; pulse 78. Wound septic; fomentations four-hourly. 27th: Temperature 100°; pulse 70. Wound much cleaner; discharge less; general condition improved. 29th: Much pain over left upper eyelid and eyebrow; eyelid was very swollen and inflamed; more discharge from entrance wound. Temperature 99°; pulse 70. 30th: Eyelid still about the same.

Dec. 2nd: Under CHCl₃ an incision was made into the eyelid; only serum escaped. A number of unhealthy granulations at both entrance and exit wounds were curetted away with a sharp spoon; wounds swabbed out with tincture of iodine and gauze drain inserted. Temperature 98°; pulse 70. 3rd: General condition much improved; eyelid much less distended and inflamed; no pain. Temperature 98°; pulse 70. 4th: Discharge very slight; no pain. From this time onward the patient uninterruptedly progressed, and was discharged to hospital ship on the 13th inst. with wounds practically healed and no evidence of facial paralysis.

CASE 4.—Colonel, R.F.A., admitted on Oct. 23rd, 1914, with a compound comminuted fracture of the right parietal bone and hernia cerebri; there was a hole in the parietal bone about the size of a shilling piece; left hemiplegia; semi-conscious. Temperature 99.8° F.; pulse 60. At operation the wound was opened up; all fragments of loose bone were removed, the bony opening slightly enlarged, and pressure relieved. The wound was closed and gauze drain inserted. 26th: Left leg moves fairly well; still paralysis of face and arm. Temperature and pulse normal. From this date to Nov. 19th progress was very satisfactory, temperature and pulse remaining normal. Was seen by Colonel Makins, and later by Colonel Sargeant, who both expressed themselves as very satisfied. Nov. 19th: Scalp wound healed; no hernia cerebri; partial paralysis of left arm and very slightly indeed of left side of face; leg completely recovered. Can raise left arm a little from the shoulder, unable to flex elbow or wrist, has slight grip with the fingers. Mental condition unimpaired; able to walk about ward with a little help. Discharged to hospital ship.

CASE 5.—Corporal, Seaforth Highlanders. Compound comminuted fracture of skull from rifle bullet. Entrance and exit wounds, both septic. The entry wound was quite small and situate in the frontal bone about 3 inches vertically above the inner canthus of the right eye. The exit wound was a large gaping hole in the temporal region about the size of a half-crown piece; this wound was situate about $\frac{1}{2}$ inch to the left of the left eye and lying both above and below that level and piercing both the frontal and malar bones. Brain matter could be seen oozing from both wounds, and especially the exit wound, and an instrument could be passed from one wound to the other without feeling any solid brain matter. Temperature 101° F.; pulse 110; left eyeball collapsed.

Operation a few hours after admission (Nov. 9th, 1914). The two wounds were joined together by a semicircular incision, and it was found that the intervening bone was shattered. All the fragmented bone was removed, which included the greater portion of the frontal bone, including the supraorbital plate, a portion of the malar and the temporal bones. The lacerated brain tissue was attended

to, the wound stitched up, the exit hole being left for drainage. The collapsed eyeball was left for the time. Wound dressed with iodine and alcohol.

Nov. 10th: This morning the patient was quite conscious; complains of very little pain; good deal of oozing of soft brain tissue. Temperature 103°; pulse 126. On visiting the wards about midday the junior surgeon was greatly surprised to see the patient reading the daily paper. 11th: Patient somewhat improved, but drowsy. Temperature 101°; pulse 100. 12th: Patient much more somnolent and was with difficulty aroused to take nourishment. Temperature 100° (evening 103°); pulse 100. 13th: Temperature 104°; pulse 94. 14th: Patient died.

This case is quoted as illustrating an enormous amount of brain and bony destruction which took place and the general condition of the patient for the succeeding five days, which was much more satisfactory than would have been thought possible.

CASE 6.—Private, R.E., admitted on Nov. 16th, 1914, with a compound comminuted fracture of the skull, septic, caused by a shrapnel bullet. The entry wound was situated at a point about 3 inches vertically above the external auditory meatus on the left side and the exit wound at a point over the posterior border of the right parietal bone about the middle. Entry wound in bone was about the size of a two-shilling piece and the exit wound was rather larger. The patient was delirious and talkative; did not answer questions. No paralysis; knee-jerks exaggerated; Babinski's sign on both sides; no ankle clonus; tended to draw legs up; abdomen retracted; dermatographia. Pupils equal and contracted, reacted to light; ecchymosis of left eye. Temperature 102.2° F.; pulse 110.

Nov. 17th: Operated on; a semicircular incision was made extending from the region of the entrance to the exit wound. A fissured fracture was seen extending between the two openings and others radiating therefrom. A number of loose pieces of bone and spicules were removed, and a bony fragment 2 by 1 inches, which was partly embedded in the brain substance, was extracted. The dura and lacerated brain were attended to and the wound sutured and drained. Temperature 101.8° (evening 98.6°). 18th: Still delirious. Temperature—18th, 98.6° (evening 101°); 19th, 99° (evening 100°); 20th, 99.2° (evening 101°); 21st, 100° (evening 104.4°). 21st: Patient died.

The notes on this case are mentioned as interesting in point of view of the symptoms arising from the injury.

CASE 7.—Lieutenant, S. Wales Borderers. Admitted on Nov. 1st, 1914, with two bullet wounds situate over the region of the left parietal and occipital bones, slightly above the level of the external occipital protuberance. The two wounds, the entrance and exit wounds, were about 1½ inches apart; both were small and quite clean. Very little evidence of bleeding; a certain amount of œdema of the scalp. The patient was very irritable and noisy. Temperature normal; pulse 84. Fracture? (it is impossible to determine this definitely owing to the œdema of the scalp). General treatment adopted.

Nov. 2nd: Patient's general condition the same; still irritable and restless; œdema of the scalp about the same; temperature normal; pulse 84. 3rd: Patient vomited badly this evening and was afterwards found to be entirely paralysed on the right side and the left side of the face slightly also. Consultation was held and it was decided not to operate; somewhat aphasic. Temperature normal; pulse 96. 4th: Consultation with Sir Wilmot Herringham; general treatment continued; on examination he discovered optic neuritis, more especially on the left. Temperature normal; pulse 96.

Nov. 5th: Patient worse, showing signs of compression; operated on. An area of scalp was turned down, including the wounds. Two bullet holes were seen in the skull and a fracture extending between them. The two openings were thrown into one, when it was found that the inner table was fractured for some distance around, the dura damaged, and the brain lacerated. The opening was considerably enlarged, all depressed and fractured bone removed, and the dura and lacerated brain attended to. A spicule of bone was also found wedged in the superior longitudinal sinus. This was removed and a good deal of hæmorrhage ensued, which was

controlled by plugging. After relieving all pressure the wound was sutured and drained.

Nov. 8th: The patient shows signs of improvement; paralysis, &c., still present. 10th: Plugging removed from superior longitudinal sinus; temperature and pulse normal. 13th: Morning temperature 100° F., evening 103°; not so well. 14th: Temperature (morning) 101·8°; signs of compression reappear. Under CHCl₃ again operated upon; opening in the skull further enlarged; opening in dura made more free, pressure relieved. 15th: Temperature 99°. Paralysis present only on right side; left half of face normal; aphasia (can say one or two words however). 17th: Scalp wound showed signs of sepsis; several stitches removed; carbolic fomentations four-hourly. Temperature 99·6°; pulse 70. 18th: There is a slight hernia cerebri, which is foul-smelling and septic. Temperature 103·2°; pulse 120. 19th: Hernia cerebri increasing; patient not so well, lying in a semi-conscious condition; only with difficulty aroused to take nourishment. Temperature 101·2°; pulse 108. 20th to 25th: Hernia cerebri still increasing; pulse and temperature varying very much. 26th: Hernia about size of a large orange; less septic; temperature 99·4°. 30th: General and mental condition much better; had a slight rigor this morning on the wound being dressed; understands all that is said, can smoke and enjoy a cigarette.

Dec. 4th: A great deal of fluid discharge, saturating pillow and sheets; this no doubt is issuing from the lateral ventricles. No sepsis; alcohol dressings. 5th: Consultation with Colonel Lister, who examined patient's eyes. He states: Right eye: slight swelling of right disc above and below about 1 + 1D, but measurement difficult as patient is unsteady; blurring of edges and veins full. Left eye: blurring of edge; fulness of veins; no swelling; slight evidence of optic neuritis. 5th to 9th: Temperature respectively 100·2°, 100·6°, 101·2°, 101·4°, and 102°. 9th: There has been a very considerable increase in the discharge of cerebral fluid during the last three days. It is noticed also that since the alcoholic dressings were instituted the temperature has gradually gone up and the patient has been much more restless; so changed to-night to carbolic fomentations (1 in 40). 10th: Temperature 99·6°; some improvement; not so restless. Dec. 13th: Patient much brighter and better. He cannot speak, but understands all that is said to him and takes more interest in his surroundings. With pencil and paper he makes an effort to write with his left hand. Hernia is receding, quite clean, is firmer and fairly smooth. 15th: Patient not so well. Temperature 102·6°; pulse 136, regular and weak; had a bilious attack. Seen by Colonel Sargeant and Dr. Holmes, who expressed their satisfaction of the case; advised treatment to continue; prognosis uncertain. 16th: Temperature 101°; pulse 118, stronger. Hernia still receding; no evidence of any discharge of cerebral fluid. Can move right leg slightly, and can turn himself in bed. 23rd: Patient was evacuated to hospital ship. Much better in himself; still had paralysis and aphasia; movement in right leg much more pronounced. Hernia cerebri has receded now to a position about half an inch above the level of the scalp. The convulsions on the surface have completely disappeared, giving an appearance of a smooth flat growth.

I have reported this case at some length as an interesting condition of hernia cerebri following operation.

I should like to express my indebtedness to Colonel Makins, Colonel Lister, Colonel Sargeant, and Major Hudson for their unvarying kindness and advice; and I especially wish to express my gratitude and appreciation to Captain Radley, my assistant surgeon, under whose care many of these cases were, and to Lieutenant W. M. S. Robinson, who also had charge of some of the cases, and who collaborated with me in issuing these reports.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—

This Fund has recently received a cheque for £500 from Sir John Ellerman, Bart., given as an annual subscription to be terminated a year or two after the war, the intention being to assist the hospitals over a period during which there is considerable fear of a material reduction in subscriptions and donations.

AN UNUSUAL RUPTURE OF THE MITRAL VALVE.

By ALEX. MILLS KENNEDY, M.D. GLASG.,

ASSISTANT TO THE MUIRHEAD PROFESSOR OF MEDICINE, UNIVERSITY OF GLASGOW; DISPENSARY PHYSICIAN, GLASGOW ROYAL INFIRMARY; PATHOLOGIST TO THE GLASGOW MATERNITY AND WOMEN'S HOSPITAL;

AND

JOHN B. McDUGALL, M.B., CH.B. GLASG.,

RESIDENT HOUSE PHYSICIAN, GLASGOW ROYAL INFIRMARY.

(From Professor W. K. Hunter's wards, Glasgow Royal Infirmary.)

ON a few rare occasions rupture of a cardiac valve has been attributed to strain, and in such cases the valve may be healthy, although more probably there is some pre-existent disease. A diseased valve may rupture as a result of a strain, but more frequently there is no history of strain and the rupture is but an incident in the progress of the disease. In such cases there is an acute endocarditis of the malignant or ulcerative type affecting the valve, which in its progress causes the formation of an aneurysm on the valve, and this eventually gives way under the pressure of the circulating blood. The resulting incompetence and effect on the circulation are variable.

It seems to be generally assumed that infection of a valve in endocarditis takes place directly from the blood circulating through the heart, and that in simple endocarditis the vegetations are usually confined to the lines of contact of the cusps, whereas in the malignant form the endocarditis is characterised by, among other things, its tendency to affect parts of the valve other than the lines of contact. Further, malignant endocarditis has a tendency to spread to parts of the cardiac musculature, notably the posterior auricular wall and the chordæ tendineæ in mitral cases.

In an investigation into the pathology of cardiac arrhythmia, which one of us (A. M. K.) has been engaged upon for a number of years, a prominent feature of cases of endocarditis has been the marked inflammatory reaction present in the cardiac tissue at the bases of the inflamed valves, and this, striking inwards, involved the subjacent a.-v. node or bundle, producing a corresponding disturbance of the cardiac rhythm. The case herein recorded is one of malignant endocarditis, not valvular but mural, in which inflammatory reaction in the cardiac tissue at the base of the mitral valve was so acute that necrosis occurred and the cusps were torn off from their attachments to the wall.

The patient was a moderately well-nourished although sparely built man of 61 years of age, who was brought into the Glasgow Royal Infirmary in an almost unconscious condition one night at 11.40, having been found in this condition on one of the city bridges about half an hour previously. No history of the man could be obtained at this time. The body surface generally was cold and pale; he could only be partially roused, and in answer to questions uttered only unintelligible grunts. There was no odour of alcohol or any other drug from the breath, and no evident paralysis could be found anywhere. There was an old operation scar in the right inguinal region, and other old scars on the left forearm and right thigh, but with the exception of two small bruises on the back of the right hand and on the front of the left tibia, there was no other evidence of recent injury. The pupils were medium in size, reacted normally to light, and the conjunctival reflex was present. The right conjunctiva was congested, and there was a little hæmorrhage into the left. The tendon reflexes were present, but the responses were sluggish. Urine had apparently been passed involuntarily, and the bladder was

found empty on catheterisation. There was no œdema anywhere. On being put to bed the patient assumed the dorsal decubitus position, and was somewhat restless, but at no time unmanageable. The pulse was regular but extremely feeble and soft, with a rate of about 78 per minute, although the beats were difficult to count. The superficial cardiac area extended to the right beyond the right sternal margin, and to the left a little external to the mid-clavicular line; upwards it reached the third rib. The cardiac sounds were extremely faint and difficult to hear in all the areas, and no murmur was elicited. The respirations numbered 32 per minute, and were shallow and mostly abdominal. The lungs were resonant all over, and the breath sounds vesicular, with some prolongation of expiration, and accompanied by occasional rhonchi. Nothing abnormal was detected in the abdomen, and neither the liver nor spleen was enlarged. Hot-water bottles were placed around the patient in bed, and by midnight he fell into a sound sleep, from which he never awoke. The pulse became more feeble and rapid, the beats being almost imperceptible, and the cardiac sounds became extremely distant and approximated, so that first and second sounds were indistinguishable one from the other. The respirations remained much about the same; the temperature never rose above 97° F., and gradually deepening coma ensued, from which the patient died at 9.10 on the following morning—eight and a half hours after admission.

An interview with the man's relatives was obtained later, and from that it was ascertained that for many years he had been living apart from his wife in a common lodging-house, doing little work, but drinking heavily on the money allowed him by his family. No history of his present illness could be obtained and nothing further in his medical history beyond the fact that he had suffered from some urinary trouble.

At the necropsy dense adhesions were found in the abdomen, mostly in the right iliac region, but extending up to and over the surface of the liver. Just below the brim of the pelvis the old adhesions formed a particularly dense mass surrounding the vessels and ureter of the left side. Just above this mass there was irregularity, with slight aneurysmal dilatation of the common iliac artery. The mass produced a definite but not tight stricture of the ureter, and from here upwards the ureter was tortuous and much dilated, in places being about an inch in diameter. The pelvis of the left kidney was dilated, forming a hydronephrosis, and the kidney substance itself showed marked cloudy swelling, but not much atrophy. The right kidney showed cloudy swelling only. The bladder was hypertrophied and there was a number of raised patches apparently of some infection in the trigone. The liver showed fairly marked cloudy swelling and the spleen was soft and congested—of the septic type; the lungs were emphysematous and both bases were very œdematous, hypostatic congestion at the base of the right being very marked. There was slight œdema of the brain and meninges, with some chronic thickening of the pia arachnoid over the convexity, but there was nothing further of note to be made out except in the heart.

Examination of the heart revealed a "milk spot" on the front of the right ventricle and also some superficial strands of fibrosis along the courses of the coronary arteries, which were tortuous but not thickened. The tortuosity was rendered conspicuous by the diminished amount of fat that was present on the surface of the heart. The cardiac muscle showed brown atrophy and slight fibrosis. There was slight fibrous thickening with occasional very slight calcareous deposition along the line of attachment of the aortic valve, and extending downwards for about an inch there was diffuse superficial fibrosis of the endocardium of the left ventricle. At the base of the left posterior aortic cusp, in relation to the anterior mitral cusp, there was an area of calcification about the size of a pea, extending from the valve segment into the subjacent cardiac tissue. The aortic cusps showed nothing else abnormal, and the valve was competent. At the base of the mitral valve was a button-hole rupture, due to the cusps having been separated from the cardiac septum along their line of attachment. (Fig. 1.) The rupture was situated towards the right side of the valve, involving the junction between the two cusps, two-thirds of it being in the posterior cusp and one-third in the anterior cusp. The edges were somewhat ragged; its total length

was about three-quarters of an inch, and its greatest breadth about three-eighths of an inch. There was very slight patchy chronic thickening towards the edges of the mitral cusp in the neighbourhood of the rupture, but no evidence of acute endocarditis on the valve segments. Corresponding with this rupture was another in the cardiac septum immediately below, and parallel to, the auriculo-ventricular ring. This rupture also was about three-quarters of an inch long and extended about three-eighths of an inch deep; its edges were rough, and apparently it marked the site of attachment of the separated valve segments. There was no evidence of aneurysm having been present on the valve. The left auricle was much dilated, and on its posterior wall, about three-quarters of an inch directly above the posterior mitral cusp, there was a patch of ulcerative endocarditis (Fig. 1); it was about the size of a sixpenny piece, and the vegetations composing it were small and granular-looking. Midway

FIG. 1.

Shows the two patches of malignant endocarditis on the posterior auricular wall and the rupture in the mitral valve. Through this the breach in the cardiac septum, with its irregular margins, can be seen. Also shows one of the moderator bands and the fibrosis at the tips of the papillary muscles.

between this patch and the ruptured cusps was another patch on the wall of the auricle. It was very minute, however, showing only five or six vegetations. (Fig. 1.) The papillary muscles showed well-marked superficial fibrosis of their tips, and three moderator bands were present in the left ventricle. The right ventricle was much dilated, and the right auricle greatly so, but there was no apparent hypertrophy of any of the cardiac chambers.

Different portions of the heart were examined microscopically and they all showed slight brown atrophy of the cardiac muscle. One piece was taken from the cardiac septum to include the auricular and ventricular portions bordering the rupture. It was cut out at right angles to the rupture, across its centre, and extended from the surface inwards the full depth of the tear. On microscopical examination of this piece (Fig. 2) it was at once evident that the breach was due to acute inflammation of pyogenic origin involving this part of the septum. The tissues were congested and infiltrated with polymorphonuclear leucocytes in abundance. These were present in greatest numbers as a broad zone towards the ruptured surfaces and the surface of the septum. Superficially the cardiac tissue was necrotic and showed in places some fibrinous deposition. The acute inflammation and necrosis involved both auricular and ventricular portions of the septum, but was much more marked in the latter; it extended the whole depth of the rupture, but gradually faded off beyond its immediate neighbourhood. The cause of the inflammation was found to be streptococci, which were present in great numbers. They were in short chains and most abundant at the surfaces.

The lesion had all the appearances of a malignant endocarditis involving the left side of the cardiac septum just below the auriculo-ventricular ring, and in which ulceration

with scanty fibrin formation was the characteristic feature. It was apparent that the breach in the cardiac septum corresponded practically with the former site of attachment of the valve segments and along which mechanical separation of them had taken place. In this region fibrosis with slight calcification was also seen. The portion of posterior auricular wall taken in the neighbourhood of the endocarditic vegetations showed a marked polymorphonuclear leucocytic reaction just below the surface. A portion from a papillary muscle showed fibrosis at the tip and elsewhere, which towards the surface was infiltrated with inflammatory cells.

FIG. 2.

The lower portion of the cardiac septum bordering the rupture. Shows the necrotic surface with zone of leucocytic infiltration below. The upper surface is the lower margin of the breach in the cardiac septum and the left side is the surface of the ventricular septum. The upper left hand corner shows the remains of the attachment of the mitral valve. ($\times 90$.)

It is unfortunate that no recent history of the patient was obtainable, but from the naked-eye and microscopic examination of the heart it seems highly probable that the malignant endocarditis was of short duration. In all probability the source of the cardiac infection was the lesions in the bladder. We do not know whether the man had been exerting himself any more than by walking, but in any case the pathological process in the cardiac septum was sufficient to give rise to "spontaneous" separation of the cusps. It seems likely that owing to the large size of the rupture its occurrence would be associated with loss of consciousness due to the sudden upsetting of the circulation, and that death ensued nine hours later from cardiac failure.

But apart from the rupture there is another interesting, perhaps more important, feature of the case—viz., the occurrence of a characteristic malignant endocarditis involving the walls and not the valves of the heart. In this respect there is a similarity to a case observed by one of us (A. M. K.) a few years ago, which is quoted by Cowan.¹ This

¹ Diseases of the Heart, London, 1914.

was a case of septicæmia in which an abscess formed in the interventricular septum and reached the interior of the right ventricle immediately beneath the septal cusp of the tricuspid valve. The centre of this cusp became involved by direct infection, and a perforation measuring nearly a centimetre in diameter followed; the margins of the cusp were not affected by the endocarditis.

We are indebted to Professor Hunter for permission to publish the case, and to Professor J. H. Teacher for permission to investigate the heart.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

HEMORRHAGE AFTER DENTAL EXTRACTIONS.

BY PHILIP GELL GARRETT, M.B., B.S. DURH.,
M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.

DURING the first half of last year I had an unusual number of cases of bleeding following tooth extraction. The most recent case was followed by death, and is, I think, worth recording.

The patient was a young married woman, aged 32, the mother of two children; she was tall but somewhat frail, and was the subject of some mitral regurgitation. She suffered from neuralgia, and as her mouth contained a number of stumps she was advised to have them removed. On the morning of June 19th, 1914, she came to see me because her gums were bleeding. I found that the blood issued from the socket of an incisor tooth which had been removed the day previously. The extractions were made about 6 P.M. on June 18th. The husband says that there was no bleeding at bedtime. At 6 A.M. on the 19th she found that her mouth was bleeding, and between 6 and 8 o'clock she lost quite a considerable quantity of blood. Between 9 and 10 A.M., when she visited me, I found a good deal of blood-clot, but bleeding soon stopped after pressure was applied. I saw her later in the day, when there was still no bleeding. She came to see me about 8 P.M., and was still all right. She took a motor-bus home, and then seemed to be in her usual health and spirits. At 1 A.M. on June 20th to her husband she appeared as usual. At 4 A.M. he awoke and found her with her face set. I was sent for and she was dead. I notified the coroner of her death and he decided to hold an inquest. A verdict of "Death from heart failure" was returned.

A few somewhat important points are to be gathered from this and other cases of the sort. 1. I am told that 40 per cent. of those who extract teeth are not on the Register. 2. Local anæsthesia is obtained by the injection of preparations containing powerful drugs. In the case quoted the preparation used was obtained from a firm of great repute. Most of these preparations contain cocaine and adrenalin, and it is very doubtful whether many of the operators know anything more of the action of these potent drugs than that they relieve pain and for a time check bleeding. 3. Many dentists think that they do their duty by a patient if they keep him under observation for about 15 minutes. Another patient had teeth extracted at 7 P.M., and there was so much bleeding hours after that

I was sent for. My assistant saw her at 4 A.M., and remained with her for half an hour. 4. There is not only danger from hæmorrhage, which may come on hours after the patient has left the dentist, but there is also the danger of absorption of a poisonous dose of cocaine. It should be added that the half dozen patients whom I have in mind were probably distributed amongst at least four different operators.

Earl Shilton, Hinckley.

AN INSTRUCTIVE CASE OF TUBERCULOUS PERITONITIS.

BY THOMAS BODLEY SCOTT, M.R.C.S. ENG.,
L.R.C.P. EDIN.

THE patient, a man aged 40, who had for some time had chronic tuberculous trouble in the chest, the left lung being in a fibroid condition, gradually developed general peritonitis. There was much pain, and tenderness on pressure. The temperature rose to 102.6° F. Dyspepsia, which was very acute, took the form of hyperacidity with occasional vomiting. In a few days a large quantity of ascitic fluid formed. There were no œdema in the legs, no jaundice, and no albuminuria, so the fluid was clearly the result of peritonitis only. On paracentesis about 2 gallons of fluid were withdrawn. This gave but temporary relief. In view of the patient's very grave condition laparotomy was advised as his only chance. To this he wisely consented. The operation was performed by Mr. Bernard Scott, of Bournemouth. He found acute peritonitis with tubercle manifest in every direction. The intestines were matted together and were in many places adherent to the anterior abdominal wall, so much so that any further paracentesis would have been very dangerous. After some trouble the adhesions were sufficiently broken down to allow of free drainage and evacuation of the ascitic fluid which had collected in pockets. The peritoneal cavity was exposed to the air for about 15 minutes; no saline injections were used. The wound was closed, no drainage-tubes being left. The patient made an uninterrupted recovery. All signs of peritonitis have gone. There are no swelling and no tenderness. The temperature has come down to 99°, and he is able to take outdoor exercise with comfort. During his convalescence from the operation he was lying out of doors in a balcony all day. The dyspepsia has gone, and the action of the bowels is normal.

This is the third case of general tuberculous peritonitis in the last 20 years that I have seen cured by laparotomy. The explanation is very difficult, but accumulating evidence shows, I think, that all such cases should have the opportunity of taking the benefit of this safe and simple operation.

Bournemouth.

DONATIONS AND BEQUESTS.—The Chelsea Hospital for Women has received from the estate of the late Mr. Edward Baker a sum of £4788 4s. 1d., of which £2640 are allotted to the rebuilding fund and the remainder to the general fund.—The late Mr. Birkenhead Clegg, of Backford, Cheshire, bequeathed by will £500 to the Chester General Infirmary, £300 to the Wigan Infirmary, and £200 to the Convalescent Home at Parkgate.—Under the will of the late Mr. William Stirling, of Muir-of-Ord, Ross-shire, and London, the testator left £300 each to the Northern Infirmary, Inverness, and the Ross Memorial Hospital, Dingwall, and £200 to the Cumberland Infirmary, Carlisle.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

Discussion on the Epidemiology of Cerebro-spinal Meningitis.

Professor Sir WILLIAM OSLER in opening a special discussion on this subject on Feb. 26th hoped that the debate would perhaps allay the growing apprehension on the part of the public and would stimulate scientific interest in the problems in one of the most remarkable of epidemics. He dwelt with four points. First, the epidemic prevalence during the nineteenth and the early part of the present centuries. Hirsch divided the epidemics of the last century into four great periods. A fifth began early in the "nineties," characterised by a sharp outbreak in New York in 1893, during which year also there was an epidemic in the State of Maryland localised to certain mining towns. In 1897-98 the disease reappeared, and there was an outbreak in Baltimore and severe epidemics in Germany and Italy. For the past 20 years there had been a wider prevalence of the disease than at any period since our first knowledge of it in 1805. The best indication of this progress might be had from the striking increase in the literature as shown in the "Index Medicus." New York suffered severely in 1904-05, Silesia in 1905-07, France in 1908-10, and the South-Western States of America in 1911. During this century the feature of special interest had been the increasing prevalence of the disease in the United Kingdom, which could scarcely be said to have suffered in the nineteenth. The first outbreaks of importance appeared in Ireland and Scotland in 1907-08. In Glasgow there were 1238 cases with 838 deaths, and in Belfast 705 cases with 548 deaths. For the past three years there had been a steady increase in the number of cases notified, reaching 310 in 1914. This winter, with the concentration of soldiers in camps and the unusually bad weather, outbreaks had occurred in many places. The question had to be determined whether, as had been suggested, the disease had been imported with some of the overseas troops; but Professor Osler thought that as there had been an outbreak in 1913-14 in the West of England and with the increasing prevalence this could not be maintained. As usual, the morbidity rate was low in the community, but the mortality rate was high, ranging from 50 to 75 per cent. of the cases. As a killing disease cerebro-spinal fever was insignificant in comparison with pneumonia, with which as an epidemic it had many resemblances—the constant presence of sporadic cases; the occurrence of small foci in a single house, in a barrack, or in a gaol; the special prevalence of epidemics among soldiers; the seasonal relations; the mild grade of contagiousness; the transmission by carriers; and the variability of the germ. The second point he referred to was the variability of the meningococcus—a germ with specific immunity reactions, agglutination, complement deviation, and opsonisation. Like the pneumococcus, the germ presented several strains with marked biological differences, and he referred particularly to the parameningococcus, which, culturally indistinguishable, presented marked serological differences. The third point was the sources of infection, which had been very obscure until the discovery of the existence of sporadic cases of the disease and the presence of carriers. The sporadic form occurred not only as the "posterior-basic meningitis," as it is called, but it attacked not very infrequently young adults. It seemed probable that the meningococcus was a widely spread organism in all communities as a germ of low virulence. The most important of the studies in recent epidemics had been to show the wide prevalence of carriers, varying from 10 to 50 per cent. in the immediate entourage of a patient, and the existence of such individuals during epidemic prevalence who had themselves never been directly exposed. Healthy persons carrying the germs transmitted to others in the ordinary contact of intercourse, in the use of common eating utensils, in kissing, in the contact of soiled hands, and the contamination of food by carrier cooks. A measure of special susceptibility in the individual

must be assumed, and just as was the case with pneumonia only a very small percentage of carriers were attacked. The recurrence in cycles was very difficult to explain, but it was a character which the disease shared with many others. Possibly certain conditions favoured increased virulence, and an increased susceptibility on the part of the individual might be caused by depressing influences of overcrowding and bad weather. The sudden onset, the fulminant cases, the presence of the meningococcus in the blood favoured the view of a primary blood infection. Lastly he dealt with the question of serum-therapy, which had been remarkably successful in some outbreaks, as shown in the statistics of Flexner and Robb in the Belfast epidemic and in the recent outbreaks in the South-Western States of America. The treatment was directed towards the destruction of the organisms themselves in the meninges, acting by bacteriolysis and phagocytosis, at the same time neutralising the poisons. He referred to the technical difficulties in carrying out the treatment and to the existence of refractory, so-called fast, strains of the germ. As an outcome of recent studies at the Rockefeller Institute the use of a polyvalent serum was suggested, and it was satisfactory to know that steps had been taken for the manufacture of this on a large scale for use during the present outbreak.

Dr. J. C. G. LEDINGHAM, in reopening the adjourned discussion on March 5th, said: What I have got to say in regard to the Bacteriology of Epidemic Cerebro-spinal Meningitis is doubtless only too familiar to many of you here present, but it is perhaps well in a general discussion of this kind to restate briefly certain points in connexion with the biology and distribution of the meningococcus which have a distinct bearing on the epidemiology of the disease. The meningococcus of Weichselbaum is universally regarded as the essential specific cause of epidemic cerebro-spinal meningitis, as also of certain forms of sporadic meningitis. It belongs to a small group of Gram-negative diplococci, the only other important member of which is the gonococcus. In many relationships, and especially the serological relationships, it bears a close family resemblance to the gonococcus, and if the distribution of the gonococcus were other than it is, there is no doubt that the difficulties in differentiation, surmountable though they are, might be greatly increased. Records of cerebro-spinal meningitis as we know it are wanting before the year 1805, and the daring hypothesis has been put forward that the meningococcus may have arisen as a mutant form of the gonococcus, with its seat of predilection in the meninges instead of the genital tract. It would be idle, however, to speculate further on this point at present as research is hampered by our inability to communicate either cerebro-spinal meningitis or gonorrhoea as we know them to laboratory animals. The serological and other affinities that exist between the meningococcus and the gonococcus find an interesting parallel in those that exist between the bacillus which causes pseudo-tuberculosis in rodents and the bacillus of human plague. The meningococcus is a delicate short-lived organism, and requires for its successful isolation and for a variable time after isolation the presence of serum, ascitic fluid, or some such substance in the nutrient medium. Later it can grow without these additions, but it still retains certain properties which mark it off as an organism which cannot under any circumstances lead a saprophytic life outside the human body. These properties are its great susceptibility to (1) cold, and (2) to drying. It will not grow below 25° C., and cultures kept at room temperature very rapidly die out. If no precautions are taken against drying the organism dies out even at 37° C. in a few days, but if such precautions are taken it has been found possible to keep the organism alive for so long as six to ten months. The observations of various authors vary somewhat, and it is unnecessary to cite details, but all are agreed that the meningococcus is an organism which is notoriously susceptible to external influences of the kind mentioned. When found in the lumbar fluid of cases of meningitis the meningococcus is readily identified by its Gram-negative character and its frequent intracellular disposition. After isolation the growth is distinguished by its emulsibility in saline, its action on certain carbohydrates, and its behaviour towards an agglutinating serum. As organisms other than the meningococcus are only very rarely met with in fresh lumbar fluid samples from cerebro-spinal cases

some of these tests may legitimately be dispensed with, especially if work is pressing, but in the case of suspicious organisms isolated from the naso-pharynx of cases or carriers, identification tests have necessarily to be more strict in view of the fact that other Gram-negative diplococci, such as the micrococcus catarrhalis and the group of chromogenic diplococci, are liable to occur in this situation. The criteria employed for the identification of meningococci from the naso-pharynx have probably not always been of a uniformly strict character, and this fact has undoubtedly to be taken into consideration in appraising the percentages obtained by various workers who have searched for carriers either during the epidemic season or at epidemic-free periods. These points will no doubt be dealt with by other speakers who have recently had field experience in this matter. Here I desire to comment on the agglutination difficulties. It would be exceedingly desirable to have an agglutinating serum which would act with some uniformity against meningococcal strains of various origin. In hunting for carriers it would be invaluable, but so far the difficulties presented by the fact that a considerable number of strains are relatively inagglutinable have not been surmounted. A serum prepared by immunisation with one strain may agglutinate only a small proportion of other strains. For example, Elser and Huntton in America tested a monovalent serum against 65 strains with the result that 25 or 40 per cent. of them were not appreciably affected. Similar results have been got by Arkwright and other workers. On the other hand, some of these inagglutinable strains may have slight but definite absorptive powers and may when injected into animals produce sera which affect agglutinable strains, though remaining without action or with only slight action on the homologous organisms. It is possible, however, that these difficulties may yield to further research which the present outbreak will doubtless stimulate, but it has to be remembered that in the coccal group generally these serological difficulties due to apparent high specificity of the individual strain are constantly met with—e.g., in the case of the pneumococcus. The phenomenon is not confined to this group however, as very occasionally strains of *B. typhosus* are met with which are relatively inagglutinable but which are able to produce agglutinins for other strains. With regard to the distribution of the meningococcus, it has never been isolated from dust, air, or fomites generally; and, indeed, its short-lived character renders very remote the possibility of its transmission by such media. Apart from the actual case of the disease, the meningococcus is found in the naso-pharynx of a certain proportion of persons living in more or less contiguity with cases. This type of carrier will be dealt with by other speakers. Here I should like to refer to its occasional presence in the naso-pharynx of healthy persons at epidemic-free periods. In the book on the carrier problem by Arkwright and myself¹ a list of observations on this point is found, and Sophian in his book² publishes a similar list. Some observers have found a small percentage of carriers in such populations, while others have found none, but the total number of cases examined has not been large. The only large series is that by Mayer and Waldmann (1910), who examined 9111 men in the Munich garrison at an epidemic-free period and found roughly 2 per cent. of carriers amongst them. In a recent paper in the *British Medical Journal* Sir William Osler quoted these figures and added a point of exclamation, the inference to be drawn probably being that he (Sir William Osler) was inclined to subscribe to Mayer's sweeping generalisation from his figures—viz., that the meningococcus was a ubiquitous organism occurring in 2 per cent. of normal people. This question is, of course, a most important one. If one were to accept a generalisation of this kind it would amount to placing cerebro-spinal meningitis on the same plane as pneumonia where epidemiology does not come in—i.e., if we accept the current view that a person gets pneumonia by infection with a strain which has been growing saprophytically in his respiratory tract. Now it must be said that at the time some doubt was cast on these observations of Mayer by his own compatriots, and in a footnote to his paper Mayer refers to this feeling of scepticism. But probably the feeling was one rather of

¹ Ledingham and Arkwright: The Carrier Problem in Infectious Diseases. London: Edward Arnold, 1912.

² Sophian: Epidemic Cerebro-spinal Meningitis. London: Kimpton, 1913.

disagreement with his generalisation above referred to. In my view there is no reason to doubt the figures, but in appraising them one has to remember that the population examined was one in which cases had been occurring yearly. It is therefore not at all improbable that some of his carriers revealed at the meningitis-free period had either been chronic carriers for some months, while others had been infected by such carriers. As a matter of fact, Mayer admits that 4 out of 35 persons who were carriers during the meningitis season proved to be still harbouring the meningococcus at the meningitis-free period. The way in which one carrier gets surrounded by a zone of carriers has been very clearly demonstrated by Selter, whose observations are to be found in the book on the carrier problem. The presence of such carriers at an epidemic-free period is indeed necessary to explain the peculiar manner in which cerebro-spinal meningitis springs up in areas between which and previously infected areas no apparent connexion can be traced. The chronic carrier with probably a zone of carriers round him act as the bridge between one epidemic and the next. A generalisation therefore like that propounded by Mayer is entirely unjustified at the present time, and is calculated to give a false sense of security to the general and medical public.

MEDICAL SOCIETY OF LONDON.

Outbreak of Toxic Jaundice of a New Type among Aeroplane Workers.

A MEETING of this society was held on March 1st, Sir J. BLAND-SUTTON, the President, being in the chair.

Dr. W. H. WILLCOX, Dr. B. H. SPILSBURY, and Dr. T. M. LEGGE contributed papers on an Outbreak of Toxic Jaundice of a New Type among Aeroplane Workers. Dr. Willcox dealt with the clinical and toxicological portion, Dr. Spilsbury with the pathology, and Dr. Legge with the industrial aspects of the condition. Dr. Willcox's paper appears in full in our present issue.

Dr. E. A. COCKAYNE spoke of the close similarity between this condition and that of the epidemic catarrhal jaundice with which he was familiar. The clinical features and pathological changes were closely parallel, and in the latter disease during an epidemic some cases also only manifested intestinal symptoms without vomiting.

Dr. J. M. BERNSTEIN said that in one case he had found leucin in the urine, and in a severe case an enormous amount of urea. He had examined two rabbits which had been running about in a workroom where doping was done. One showed degenerative changes in the liver, but no fatty changes; the other no changes whatever. Two others had been exposed to the fumes of dope constantly, day and night; neither showed any signs of ill-health. More dope was then used, and some was mixed with their food; one was killed, but no changes were found. He did not think that these investigations could be held to negative those of the readers of the papers.

Dr. F. J. POYNTON referred to the fact that there were many mysterious cases of jaundice cropping up at the present time. Five nurses had suffered from it in one ward in succession. In children the jaundice ran a very long course; one had died, and parenchymatous degeneration and shrinking of the liver had been found.

Sir FREDERIC W. HEWITT said that he was chiefly interested from the point of view of delayed chloroform poisoning. There were certain points of dissimilarity. In that condition the course was more rapid, and jaundice was less obvious, and vomiting of a material like beef-tea occurred.

Dr. WILLCOX, in his reply, said that he was not at all surprised at the negative results obtained in the case of the rabbit. He always sedulously avoided those animals in toxicological experiments, since their reaction to poisons was peculiar.

HUNTERIAN SOCIETY.—A meeting of this society was held on Feb. 24th at the Barbers' Hall, Dr. A. C. Jordan, Vice-president, being in the chair.—Dr. T. D. Lister, in demonstrating an Apparatus for Producing Pneumothorax, remarked that the procedure was based on the observation that its spontaneous occurrence in cases of pulmonary tuberculosis sometimes led to recovery. The advantage of the artificial method over the natural was that

the gas introduced was sterile. Oxygen was run in first to obviate the danger of gas embolism in case a small vein had been punctured. Certainty that the needle was in the right place was assured when first a negative pressure and then varying pressures in accordance with the respiratory movements were observed in the attached manometer. His apparatus was based on that of Dr. de Carle Woodcock of Leeds. Oxygen was obtained by acting on a solution of perborate of soda with peroxide of manganese, whilst nitrogen was obtained by drawing air through an alkaline solution of pyrogallallic acid. Ether gas was introduced into the pleural cavity by altering the relative heights of the gas holders and the reservoirs containing an antiseptic solution. A great many taps were necessary, but he had devised one central control tap with an indicator, by which the whole apparatus could be very simply worked. The cases for artificial pneumothorax needed very careful selection. The operation had been performed far too often. A suitable type of case was one where there was rapid infiltration of one lung without fibrosis or cavity formation, and in which there had been no response to ordinary methods of sanatorium treatment. In such cases where the treatment had been persisted in for a long time he had seen very favourable results. He believed that these results were due not to closure of air tubes but to diminution of the flow of blood and lymph through the diseased tissues. The number of deaths caused by the operation was very small. They were due to gas embolism or to the effect of the "pleural reflex" on the heart.—Dr. G. T. WESTERN read a paper on Vaccine Therapy, its Present Scope. He referred first to the question of protective inoculation against typhoid as one of national importance at the present time. An active and partially successful campaign was being carried on against this measure. It was the duty of medical men to be prepared with a few well-controlled statistics and effective replies to objections. He quoted some striking examples of case incidence and mortality of typhoid among inoculated and uninoculated men living under exactly the same conditions, instancing especially the experience of the 17th Lancers in India in 1905 and the French soldiers at Avignon in 1912. He had inoculated a great many people against typhoid and the following questions had been frequently put to him: Is there any danger? Will it make me ill? Can I get typhoid if I am inoculated? How long will the protection last? He dealt briefly with the answers to these questions. In dealing with the present scope of vaccine therapy Dr. Western confined himself to the use of vaccines in generalised infections or septicæmias. He did not regard these as cases in which bacteria multiplied in the blood, but rather as local infections from which they were able on account of insufficient defences to find their way into the blood stream. In undoubted cases of progressive endocarditis he had often seen benefit from vaccines, but never permanent cure. Vegetations on the damaged valves were not vascularised, and consequently blood containing antibodies could not reach them, whilst they were in the best possible position for throwing off bacteria and emboli. The mortality from puerperal septicæmia, on the other hand, could be very substantially reduced by using autogenous vaccine. The same was true of acute septic infections with lymphangitis following, for instance, a prick or small wound. Doctors and nurses were liable to these attacks, as the direct passage of an organism from one subject to another was the finest way to exalt its virulence. Active immunisation by vaccines if undertaken promptly held out the best hope of cure in such cases. Stock vaccines might be given while the autogenous one was being prepared.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Jan. 28th, Dr. E. W. Hope, the President, being in the chair.—Professor Ernest E. Glynn read a paper on the Principles and Practice of the Prophylactic Use of Typhoid and other Vaccines, in which he pointed out that man might acquire immunity to typhoid fever naturally by contracting the disease. This was associated with a great increase of antibodies, such as agglutinins, opsonins, bacteriolysins, &c., in his serum. Also animals might acquire active immunity to typhoid fever artificially by vaccines; this was also associated with a great increase of antibodies. After referring to the terrible mortality from typhoid fever in recent wars, and giving a short account of the introduction of typhoid vaccines by Wright in 1896, he reported statistics from Britain, America,

France, Germany, Japan, and Italy, which demonstrated the great reduction in typhoid fever incidence and mortality as the result of antityphoid inoculation. The objections of antivaccinationists and others were next referred to. In the author's opinion the prophylactic use of typhoid vaccine in the British army was based on sound scientific principles, and was confirmed by practical experience from all parts of the world. He vigorously denounced the opposition of the antivaccinationists at the present critical time as criminal.—After some discussion of the paper Captain W. Permewan, R.A.M.C. (T.), proposed the following resolution:—

That this meeting of the Liverpool Medical Institution expresses its strong conviction that the time has come to make antityphoid inoculation compulsory in the British army.
Further resolved—

That this resolution be communicated to the Prime Minister, the Secretary of State for War, the President of the Local Government Board, the Leaders of the Opposition, the Irish Nationalists and Labour Parties, and to the press.

This was seconded by Mr. Bickerton and carried unanimously.

Reviews and Notices of Books.

Operative Surgery: The Head and Neck, the Thorax and the Abdomen.

By EDWARD H. TAYLOR, M.D., B.S. Dub., F.R.C.S. Irel., Professor of Surgery in the University of Dublin, Surgeon to Sir Patrick Dun's Hospital. Illustrated with 300 figures from original drawings, many printed in colours. London: J. and A. Churchill. 1914. Pp. 524. Price 30s. net.

THE author tells us in the preface that he has not attempted to include in this volume all the operations which have been or may be done in the regions of the body to which he has limited his book, but only those operations which a general surgeon is likely to be called upon to perform, and a knowledge of this limitation of the subject is necessary for the reader to understand the plan of the book. We think that the author has done wisely, for if he had endeavoured to present to the reader the whole of the operative surgery of the head and neck, the thorax and the abdomen, at least two large volumes would have been needed, and he would have been precluded from giving that full treatment of the subject which he has been able to supply in this volume.

The idea of the book arose from the teaching in some post-graduate classes which Professor Taylor gave in Trinity College, and the arrangement of the work is admirably suited for the instruction of those for whose benefit it was written—namely, for the surgeon who, having had little experience in operative surgery, may be called upon to operate; he may know theoretically what should be done, but he lacks that knowledge of the practical details which is so essential to success. This book supplies those details. In the case of each operation it describes the several stages very clearly, and explains why the author prefers the course which he advises. There is a wealth of illustrations which must materially assist the reader; many of the figures represent successive stages of the more important operations, and with one or two exceptions they are original. Many of them have been drawn from stereoscopic photographs taken in the operating theatre, and colour has been freely employed.

The whole book is eminently practical, and it may be confidently recommended. It is a credit to the surgery of the kingdom. A word is also deserved on the manner in which the book has been produced; the printing is excellent.

Electric Cooking, Heating, Cleaning, &c.: Being a Manual of Electricity in the Service of the Home.

By "Housewife" (MAUDE LANCASTER). Edited by E. W. LANCASTER, A.M.Inst.C.E., M.Inst.E.E. London: Constable and Co., Limited. 1914. Pp. 338. Price 3s. 6d. net.

So few householders using the electric current for lighting purposes, apart from its applications to heating and cooking, understand even the simplest technique of the system that we wonder greater efforts have not hitherto been taken to enlighten them. The majority of electricity consumers are quite in the dark as to what the current is, how it is controlled, measured, and most effectively employed. With gas it is different. Gas is an entity, not a force. Its escape is obvious to everybody and its rate of consumption is easily understood. Everyone understands the expressions "so many cubic feet per hour," "candle power," "3-inch pressure," and so forth, but few comprehend the meaning of "short circuits," "earthing," "ampères," "volts," and "watts," the terms applied to electric supply. We have little doubt that this ignorance has in many cases been costly and the source of misgivings about the integrity of the supply company when the bill is presented. The book before us, while it does not convince us that the time has come when we can abandon coal or gas in favour of the electric current for both heating and lighting purposes, puts technical matters of the kind we have indicated so clearly that we strongly recommend all electricity consumers to possess a copy. The convenience, cleanliness, and hygiene of the electric supply cannot be denied, and the main consideration which militates against its general use is cost. For fuel purposes electricity so far cannot economically compete with gas or coal. The author makes out that it can, and we may forgive her enthusiasm.

The book supplies a real need in furnishing useful practical information on the principles of the electric current for heating and lighting purposes. It enlightens the consumer of electricity on many points on which he is at present ignorant, but concerning which it would be very much to his interest that he should cease to be so.

Fever: its Thermotaxis and Metabolism.

By ISAAC OTT, A.M., M.D., Professor of Physiology, Medico-Chirurgical College, Philadelphia. New York: Paul B. Hoeber. 1914. Pp. 166. Price \$1.50 net.

THE three lectures which make up the text were delivered before the sophomore class of the Medico-Chirurgical College—sophomore, an old appellation still retained, we are glad to see, in Philadelphia, meaning wise fools. Fever is a subject of maximal importance in the practice of medicine—so important, indeed, in the author's opinion, that for five-and-forty years the veteran Professor Isaac Ott has been engaged on this subject both as a practitioner of medicine and a physiologist.

The first lecture deals with thermotaxis, or the mechanism of heat regulation. The author gives a full account of his own researches, begun in 1884, to show that thermotaxis depends upon four nervous centres—two basal—the corpus striatum and the chief one, the tuber cinereum—and two inhibitory cerebral centres—the cruciate and Sylvian. There is also an account of the work of other observers on the same subject. No thermogenic centres of a marked thermic capacity exist in the pons, bulb, or spinal cord. In

the second lecture heat dissipation or thermolysis is dealt with. This is carried on by the "polypnoic centre" in the tuber cinereum, the vasomotor centre, and the sudorific centres. The polypnoic centre drives the respiratory centre to increased activity, and thus throws off more water from the lungs. The author is of opinion that the tuber cinereum has vasotonic activity—i.e., it gives tonus to the vasomotor centre. The relation of internal secretions to temperature is discussed and so is the question "Is fever beneficial?" Adrenalin is regarded as having a very potent activity in the increase of temperature when it is in excess in the blood. Hyperthermia, "protein fever," and the calorimetry of malarial fever occupy the remainder of the lecture. In the third lecture an extended exposition of malarial fever and metabolism as given by Lehacheff and Avroroff, which, the author states, "confirms his researches" made ten years previous to theirs, is presented. These authors infer that the fever rise of temperature, in a strictly physical sense, depends chiefly upon the rise of heat production. Protein, carbohydrate, fat, water, and purin metabolism in fever is then passed in review.

Summing up, the author concludes that fever consists of at least two main characters—thermogenic and toxogenic. As to temperature, there is an agent which deranges the harmony of the thermo-inhibitory, thermogenic, and thermolytic apparatuses, by which in the initial stage the metabolism of the tissues is temporarily increased. During the chill, heat dissipation is temporarily diminished; afterwards it usually follows the fluctuations of heat production. Toxins are produced which stimulate the tissue cells, hence the true theory of fever is a neuro-toxogenic process. There is no increased production of heat in the stages of continued fever—i.e., typhoid fever—only a disarranged regulation of heat.

Physicians and physiologists will read these lectures with interest and profit.

LIBRARY TABLE.

Le Traitement des Anémies. Par H. VAQUEZ et CH. AUBERTIN. (Les Actualités Médicales.) Paris: J. B. Baillière et Fils. 1914. Pp. 76. Price 1.50 francs.—In this excellent and practical little volume the authors divide all anæmias for therapeutic purposes into "chlorotic anæmia" with relatively large diminution in the proportion of hæmoglobin, and "grave anæmia" in which the red cells are reduced below 2,000,000 per cubic millimetre. As they point out, the proper antithesis to the term "chlorotic anæmia" is "globular anæmia"; but as the milder forms of globular anæmia with more than 2,000,000 red cells tend to recover spontaneously, they need but little consideration. The various forms of anæmia are described in turn in this little book, and the best methods of treatment for each are detailed. Charts showing the progress of special cases are given, some at first hand, others borrowed from the literature of the subject. The various forms of treatment that have proved most successful and their results are briefly and temperately described, including preparations of iron, arsenic, 606, bone marrow, serum, transfusion of blood, cholesterolin, glycerine, the X rays, thorium-X, and splenectomy. The book is well written and full of sound practical advice, and obviously the work of experienced clinicians. It may be warmly recommended to the attention of all medical students and practitioners.

An Introduction to the Study of Organic Chemistry. By H. T. CLARKE, D.Sc. Lond., F.I.C. With diagrams. London: Longmans, Green, and Co. 1914. Pp. 484. Price 6s. 6d. net.—The author is quite definite in his view as to what a text-book on organic chemistry should be. He deals with general principles rather than with practice, and so has produced a work which, in his own words, "approaches the subject with the desire of displaying its orderly principles and structural unity." In that direction, we think, he has succeeded, because we find in his book a very clear exposition of this great branch of chemical science and an order of treatment which brings the reader step by step through preliminary considerations to complex developments. In other words, the foundations of organic chemistry will be well laid in the mind of the intelligent student who merely reads this book. In regard to practice he will gather nothing from it, but then the author is careful to add "no real knowledge of organic chemistry can be acquired without laboratory work," and we agree. But at the same time we are not going to deny the value of a "laboratory companion" or handbook setting out experimental directions. There is room, of course, for both the laboratory manual, used side by side with laboratory practice and teaching, and the text-book on "orderly principles." The latter Dr. Clarke has well supplied.

Life and Law. By MAUDE GLASGOW, M.D. London and New York: G. P. Putnam's Sons. 1914. Pp. 124. Price 5s. net.—The scope of Dr. Glasgow's book is best expressed by its sub-title, which is as follows: "The Development and Exercise of the Sex Function, together with a Study of the Effect of Certain Natural and Human Laws, and a Consideration of the Hygiene of Sex." Dr. Glasgow is evidently an ardent feminist; she has a very poor opinion of the male—e.g., p. 35: "Throughout the animal world we find the male more noisy, more emotional, more quarrelsome, pugnacious, and less self-contained than the female." Again, p. 47: "Woman lives more nearly on a plane than man; she is more sane, more equable, and better poised than he." True, this instability of the male gives rise to "that congenital abnormality known as genius, more common in man than in woman," but as against this "it is the same thing which causes the preponderance among men of idiocy, insanity, imbecility, moral deficiency, and criminality." If the unstable male who is reviewing this book may dare to say so, Dr. Glasgow's views on prostitution and possible remedies for that evil seem, so far as we can gather from them, quite sound. She acknowledges that the problem "is one which bristles with complications," and considers that the best method of dealing with the subject was the now unfortunately repealed Injunction and Abatement Law of Iowa, the provisions of which, however, she does not give. Among other suggestions she proposes education in sex matters, provision for healthful recreation for working girls, a minimum wage scale, and trade schools to teach girls to earn their living. As regards the prevalence of syphilis and gonorrhœa, she would like to see both parties to a marriage compelled to send in a clean bill of health.

JOURNALS AND MAGAZINES.

Annals of Tropical Medicine and Parasitology, Vol. VIII., No. 3.—This number of the Annals contains no fewer than 16 original articles, and extends to 272 pages of print, with numerous photographic illustrations, coloured plates, maps, and charts. The first paper is by Mr. J. M. O'Brien, of the West African Medical Staff, and in it is given a study of

some cases of yellow fever which he saw at Guayaquil, Ecuador, during a visit he paid to that notoriously insanitary seaport town for the purpose of increasing his acquaintance with the disease. Adverting to the natural immunity of infants to yellow fever now generally recognised, the author expresses the opinion that this is only temporary, but that permanent protection is acquired later on; for as they lose their infantile immunity they suffer one or more attacks of "undiagnosable" yellow fever, and thus by these "gentle vaccinations" they acquire a lifelong protection from the disease. Mr. O'Brien's paper is illustrated by a coloured plate.

—Dr. J. W. Scott Macfie and Dr. G. H. Gallagher, of the West African Medical Staff, supply a joint article on sleeping sickness in the Eket district of Nigeria, in which locality the disease is endemic; but the type of the malady is mild and spontaneous cures appear to be frequent, most of the patients being children. Although the trypanosomes can be found in the gland juice they have not yet been detected in the peripheral circulation. The parasites differ in some respects in their morphology and their pathogenicity from typical strains of *T. gambiense*. The insect vector of the disease to man in Eket has not yet been determined, but suspicion has fallen upon *Glossina tachinoides*. This interesting article is illustrated by a number of photographs, a coloured plate, and a map. Dr. Scott Macfie also contributes notes on some blood parasites collected in Nigeria, with two coloured plates.—Professor John L. Todd writes on the trypanosome of Gambian mice. In general appearance this organism much more nearly resembles *T. acromys* than any of the trypanosomes which have been found in the blood of mice.—The important subject of the granule phase of spirochaetæ is discussed in a very interesting way by Dr. H. B. Fantham, who assists in throwing some light upon the question. In his paper he places on record some recent personal results obtained by himself, more especially while working last year in Khartoum.—Dr. J. B. Christopherson, director of the Khartoum and Omdurman civil hospitals, gives details of a case of naso-oral leishmaniasis, corresponding to the description of "espundia," and of a case of oriental sore, both originating in the Anglo-Egyptian Soudan.—*Quelques Observations Préliminaires sur la Morphologie et de la Biologie de la Larve, de la Nympe, et de l'Image de l'Auchmeromyia Luteola* (Fabr.) is the title of a contribution by Dr. J. Schwetz, of Kabinda, Congo.—A joint article by Dr. J. O. Wakelin Barratt and Professor Warrington Yorke gives an account, with numerous charts and tables, of experiments on the relation of bile pigments to hæmoglobin.—An outline of the antimalaria campaign recently carried out in Formosa is furnished by Dr. J. Hatori, medical inspector under the Japanese Government, the paper being illustrated by a map and several charts.—Dr. Harald Seidelin supplies an article on *klossiella* in the kidney of a guinea-pig, with two plates. This parasite was found in an animal which had been used for yellow fever experiments at Yaba, near Lagos. Since his paper was written Dr. Seidelin has observed identical parasites in another guinea-pig from the same locality.—Several articles are next contributed by members of the staff of the Australian Institute of Tropical Medicine, Townsville. The first of these is a joint paper by Dr. A. Breinl and Dr. H. Priestly on the changes in the neutrophile blood picture of Arneth observed in children living in tropical Queensland, and the same authors contribute some observations on the blood conditions of children of European descent residing in tropical Australia, being the result of an examination of 574 school children between the ages of 7 and 15 at Townsville.—Dr. Breinl also, in conjunction with Dr. W. J. Young, discusses the circumstances under which lead poisoning occurs amongst North Queensland children. The two authors suggest that such cases may commonly be due to the inhalation of dust containing lead; they draw attention also to the fact that a number of the children who suffered were addicted to the pernicious habit of biting their finger nails.—Details of some experiments, made at the Townsville Institute, on the migration of the larvæ of *Onchocerca gibsoni* through the capsule of the worm nodules, are given by Dr. W. Nicoll.—Dr. H. B. Fantham and Dr. Annie Porter describe the morphology and economic importance of *Nosema bombi*, n. sp., parasitic in various humble-bees.—The last article is by Professor J. W. W. Stephens, and in it he continues his studies in black-water fever. He puts forward a schedule which he thinks will be found useful in recording cases of this serious affection.

British Dental Journal.—The issue of this journal for Feb. 15th contains a practical paper by F. N. Doubleday on local anaesthesia in conservative dentistry. He advocates the use of novocaine with suprarenin, using about 40 minims of a 1.5 per cent. solution. The injection should be made into the reflection of the mucous membrane from the gum to the cheek, and not into the tough mucous membrane of the gum. Details are given for the injection for the various teeth. The author advises that the cavities prepared under local anaesthesia should not be permanently filled at the time in case a small traumatic exposure has been made and passed unnoticed. He states that he has had excellent results. Mr. A. Barritt contributes a short article on dental prescribing and the new Pharmacopoeia, and Mr. J. T. Hall a note on an easily prepared root-filling.

New Inventions.

A MODIFICATION OF AN OLD TONSILLOTOME.

FOR the purpose of meeting the requirements of those surgeons who when removing the tonsil force it through the opening in the tonsillotome by a pushing instead of a pulling action, I have modified the instrument I designed

some 18 years ago. In the old pattern the blade is above the sheath, in the modified one I have placed it below. By this arrangement practically nothing but the sheath required alteration. A discussion took place a few months ago in the Laryngological Section of the Royal Society of Medicine which showed that some of the most prominent laryngologists still regard my instrument as the best. It is the simplest, it has stood the test of time, and thousands of them are in regular use. Being essentially of similar mechanical construction the modified instrument will doubtless prove as durable as the original. In this, as in other matters, however, fashions change, though the principles underlying sound mechanical construction do not.

Messrs. Mayer and Meltzer, of Great Portland-street, London, W., are the makers.

CHARLES J. HEATH, F.R.C.S. Eng.,
Late Surgeon, Throat Hospital, Golden-square, W.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Feb. 18th, Sir Francis H. Champneys being in the chair. A letter was considered from the Local Government Board transmitting a copy of an application received from the Association for Promoting the Training and Supply of Midwives for a grant in aid of their work, and asking to be furnished with the observations of the Central Midwives Board on the subject. The Board directed that the Local Government Board be informed that the objects of the association are good and its council contains many well-known names, and that the Board believes that it belongs to a group of institutions which are doing valuable work and all of which deserve encouragement. A letter was considered from the medical inspector of midwives of the City of Bristol asking whether a midwife is entitled to operate on a case of tongue-tie. The Board decided that in reply to the question whether the Board considers that the dividing of the frænum of the tongue of a new-born infant falls within the duties of a midwife, the answer be in the negative. A letter was considered from the council of the Incorporated Midwives Institute transmitting for the consideration of the Board a copy of a resolution forwarded by the institute to the Local Government Board asking that body to refuse to sanction the appointment by local bodies of unqualified and inexperienced women as inspectors of midwives and for other health work. The Board decided that the Incorporated Midwives Institute be thanked for its communication.

THE LANCET.

LONDON: SATURDAY, MARCH 13, 1915.

War and Typhus Fever.

THE recently announced death of the Director-General of the Austrian Army Medical Department from exanthematic typhus in Galicia, contracted, as it appears, in the execution of his official duty, serves as a reminder of the very close and intimate association of war and typhus fever. By the light which scientific investigation has thrown upon the etiology of this disease during the last six years this association is not difficult of explanation. In the course of protracted military campaigns in which large masses of troops are herded together mostly under unfavourable sanitary conditions, where the maintenance of personal cleanliness is almost impossible and the clothing has to be worn without a change for weeks or even months, infestation by body vermin, and especially by *pediculus vestimenti*, soon becomes inevitable. The researches of NICOLLE, of Tunis, and other investigators have proved conclusively that the actual transmitting agent of the typhus virus to man is the body louse. When, therefore, military operations are carried out by verminous soldiers in a region where this disease is endemic the probabilities of an epidemic developing sooner or later are very great.

During the Napoleonic wars at the beginning of last century typhus fever ravaged the armies in the field and carried off many victims. In the Crimean campaign of 1854-56 the malady attacked the British, French, Turkish, and Russian forces. The same experience was noted in the Russo-Turkish war of 1878, as also in the recent conflict in the Balkans during 1912-13. The colossal combat in which at the present time the armies of eight European nations are engaging, seems hardly likely to reach its conclusion without the development of a typhus prevalence in one or another portion of the assembled hosts. The operations in Eastern Europe are taking place in a region which includes two well-known endemic areas of exanthematic typhus—namely, Russian Poland and Austrian Galicia. At the present moment owing to the war our usual sources of medical information in Galicia are not available, and we cannot therefore say how much typhus fever there has been in this province since hostilities began. But this we know, that for a long series of years attacks of typhus fever in Galicia have ranged from 2000 to 6000 a year. A recent report in a medical journal published in one of the neutral countries states that in January of this year upwards of 1500 cases of typhus

fever (*Fleckfieber*) were notified in Austria and that about 1000 of them occurred in the province of Styria, where, so far as can be ascertained, no typhus had been previously reported for 20 years or more. Typhus fever has also been carried into Germany, in which for many years the disease had been extinct; and notification has been made of cases among the military and civil populations as well as among prisoners. Although the Western battlefield of Europe does not include any locality in which typhus fever is still endemic, danger, nevertheless, may arise in another way. German troops are often moved from one side of Europe to the other, and it is not improbable that German or even Austrian prisoners taken in the western area might have come from the armies operating in Galicia or Poland, ill or incubating a typhus attack just before their capture, and thus bringing the infection into the camps of the Allies. But a more immediate source of danger is one which has already been discussed lately by our French brethren in the Academy of Medicine at Paris—namely, the conveyance of the disease by native troops sent to France from Tunisia, Algeria, or Morocco, in all of which countries typhus fever remains endemic to this day. The peril of infection is largely removed by the knowledge of its existence, for thorough methods to combat it have already been arranged. The danger from typhus is much greater in Eastern Europe, though the West is not altogether without its share of risk.

Typhus fever is endemic in Turkey and Egypt, in both of which countries the allied troops are in contact with the enemy, and an epidemic might develop among our own fighting men, spreading from our prisoners, if the most elaborate precautions were not being taken. Never before in the history of the world have such enormous forces been assembled together as those now facing each other in Europe from Flanders to the Dardanelles; but it may also be added that never before have medical science and military hygiene been in a better position to cope with the dangers that may arise from typhus fever or other epidemic diseases. We may confidently rely on the Army Medical Departments of the allied armies to use all the means which science and experience have placed in their hands to avert the ravages which might otherwise occur amongst their mighty hosts. And one of the most effective means is the destruction of vermin.

The Treatment of Cleft Palate.

THE most practical problem in connexion with congenital cleft of the palate is the best method of treatment, though discussion should and will continue as to etiology. A decision as to the best method of dealing with this most troublesome deformity will be acknowledged by all to be of the utmost importance, for the affection of speech which accompanies an untreated cleft

palate is a serious handicap in after-life. In the case of many lesions or abnormal conditions the ultimate decision as to the best method of treatment may be left to general impressions derived from multifarious records, but where the records tell no common tale it is far wiser to let the decision depend on statistical facts. This is the right way in which to approach the question of the treatment of cleft palate; and in his recent Hunterian lecture (concluded in our present issue) Mr. H. BLAKEWAY, by considering the matter from the statistical side, puts the surgical profession in distinct debt to him for a noteworthy contribution to the subject.

At the present time there are two, or at the most three, methods of treating cleft palate which are in evidence, though from time to time several other operations have been brought forward. These are the methods advocated by Dr. T. W. BROPHY of Chicago, by LANGENBECK, and by Sir ARBUTHNOT LANE. Dr. BROPHY, at the Clinical Congress of Surgeons of North America, held in London last summer, explained to an interested audience his whole technique, the reasons for its employment, and his claims. He said "that the normal amount of tissue is there and should be used immediately to close what is in effect a wound," and inquired what surgeon would wait two years in order to close a wound. He laid stress on the broadness of the upper jaw in these cases of soft palate, and in particular insisted that the action of the tongue in the gap and the upward pressure of the lower jaw both produced a widening of the cleft. An interesting debate followed, in which Sir ARBUTHNOT LANE and Mr. JAMES BERRY put forward the arguments respectively for the flap method and the method of median suture, Sir ARBUTHNOT LANE attaching the same importance as Dr. BROPHY to immediate radical remedy, while Mr. BERRY considered that in the common, single or double, cleft palate, associated with harelip, while the harelip should be remedied in the earliest infancy, operation on the palate should be postponed until the second or third year of life. Mr. BLAKEWAY shows that the hypothesis on which BROPHY'S operation is founded is untenable. The well-known American surgeon holds that in a case of cleft palate the two maxillæ are too far apart by exactly the amount of the palatal cleft, and he deduces from this that the correct way to treat a cleft palate is to push the two maxillæ together at a very early age, when such a procedure is possible. Mr. BLAKEWAY, however, has proved by a series of careful measurements that in the majority of normal infants the upper alveolar borders are wider apart than the lower, and that the difference noticeable in cases of cleft palate is often not much greater than that seen in children born with fully united palates. In practice, too, it has been found that it is nearly always impossible to bring together more than the alveolar arch, while the cleft itself is very little modified,

but, of course, this narrowing of the alveolar arch is productive of improvement in the appearance of the face, produced by the bringing of the nose to the mid-line. Mr. BLAKEWAY concludes that it is possible that BROPHY'S method may be used in exceptional cases, but not as a routine operation, and with this conclusion we concur. Of the two other methods we have, first, that which was systematically practised by LANGENBECK, and secondly, that with which the name of Sir ARBUTHNOT LANE is most closely associated. To estimate the comparative value of these two methods we have to consider both the rate of mortality after the operation and the functional value of the result. The median-suture method of LANGENBECK has a very low mortality; indeed, in a series of 154 cases operated on by Mr. BERRY there were no deaths at all. On the other hand, in a series of 100 consecutive cases treated by the flap method employed by Sir ARBUTHNOT LANE there were 19 deaths. This death-rate is no disparagement to the skill of the surgeon, but must be ascribed wholly to the early age at which the operation is performed and the severity of the procedure. It is true that the advocates of the flap operation claim that there is a grave mortality from malnutrition amongst harelip children who are untreated, and that the operation soon after birth saves lives that would otherwise have been lost, but the data for such an opinion are wanting, and probably the risk of death from malnutrition has been over-rated. In this direction further figures are wanted, and the question of causation—heredity, maternal injury, even maternal impressions—should be looked into and not treated as of merely academic interest.

When we turn to the ultimate conditions we find that by either method excellent functional results have been obtained in some cases, but the proportion in which the issue is good is greater with the median-suture method, for here the cicatrization is less marked. Mr. BLAKEWAY has himself examined a large number of the children on whom these operations have been performed. On the whole, therefore, statistics point to the view that the median-suture method offers the best chance of a satisfactory outcome, and remedy is obtained with less risk to the life of the patient.

COMPULSORY NOTIFICATION OF CHICKEN-POX IN LONDON.—In October last the Lambeth borough council suggested that the incursion of large numbers of refugees and others from the continent made it desirable to make chicken-pox compulsorily notifiable, since mild cases of small-pox might be diagnosed as chicken-pox. The London County Council decided at that time not to take action, but recently cases of small-pox have occurred, and on March 9th the Council, by special resolution, made chicken-pox notifiable within the administrative county until June 30th, 1915. The Local Government Board had notified its approval in advance.

Annotations.

"Ne quid nimis."

THE SOLDIERS' FOOD.

THE prolonged hearing of a summons against Messrs. J. Lyons and Co. in respect of beef alleged to be unfit for food, but intended for troops quartered at the White City, ended in the conviction of the caterers and the imposition of the maximum fine of £50, coupled with £70 costs. Mr. Fordham, who heard the case at the West London police-court, had an early difficulty in dealing with it owing to his having omitted to point out to the defendants that they could claim trial by jury. This, however, was apparently rectified by recommencing the hearing, and the main point raised in defence was, briefly, whether unwholesome food was being prepared for the troops at the time when the Hammersmith borough council's representative first saw it or whether it had been withdrawn by the defendants' servants after detecting its condition. The evidence bearing on this point was of a contradictory character, and it would not be desirable to recapitulate and comment upon the learned magistrate's observations in announcing his decision, in view of an intimation by counsel that there will be an appeal, at which this question and the technical one indicated above may be further discussed. Mr. Fordham was himself satisfied that the defendants were to blame, and were seriously to blame, for the acts of their servants, and he concluded by saying that the Hammersmith borough council would not have done its "barest duty" if it had not taken proceedings. The council, therefore, and the medical officer of health, Mr. J. B. Howell, deserve congratulation upon the success which has been obtained by them at the present stage, and upon their intervention in a matter not likely to have come within the range of their previous experience. Before the war it might not have struck anyone that the supervision of the food of military forces, training in a particular neighbourhood owing to fortuitous convenience for billeting them, would be added as a duty to that already discharged with regard to the civil population by a medical officer of health. Whether this is wholly a good arrangement is for the consideration of the Government and of the military authorities, but we suggest to them that as they are spending money on feeding an army they should assist in providing supervision sufficient to secure the proper carrying out of their intentions. In this instance the actual arrangement in force at the White City seems to have been made between the caterers and the County Territorial Force Association for the feeding of not less than 10,000 men at the rate of 1s. 9d. per man per day. Such a rate should suffice for the provision of a sufficient supply of food not only sound but palatable, while leaving a fair margin of profit to the contractor. Has this been so either universally or even generally is a question which the British citizen would like to have answered satisfactorily. It may be an undesirable topic to investigate publicly at such a time as the present, but some day inquiry ought to elucidate it, and meanwhile

every effort should be made to remove as far as circumstances permit, any cause for complaint and any suspicion that the country is not getting full value for the money that it is expending. It is not right that soldiers should be well fed and content in one place, when elsewhere others upon whom an equal amount is being spent have good cause to complain. The fact that many do not complain, but contentedly make the best of adverse circumstances which they did not bargain for, is entirely to their credit, but does not otherwise affect the matter. The recent case in West London is not alone in calling attention to soldiers' food and the conditions under which it is supplied. Recent correspondence in newspapers has shown that regrettable waste of provisions in army camps has taken place and is taking place. The extent to which this is preventable, and the possibility of introducing better training of caterers and cooks are large questions into which we do not now go. It would be difficult to introduce general improvement with any immediate effectiveness in a matter with regard to which as a nation we are at normal times indifferent, and no one suggests that the present conditions are bad as a whole. In the British Islands economical cookery, producing palatable and wholesome results, is insufficiently studied by a large proportion of the women of the working classes, and is considered beneath the attention of men. Hence for the classes who are able to eat outside their houses foreigners have for many years done business in towns wherever the demand has attracted supply. The result with regard to cookery for the new army, in circumstances admittedly unforeseen and wholly abnormal, has been that a very large number of those who have joined it have found the nature of the food an irritating hardship. This is certainly not due to niggardliness on the part of the Government, and, indeed, the profusion which appears to characterise the whole matter is not its least serious aspect. This feature, however, may perhaps lead to the ultimate improvement which is desired by all who wish to see no hindrance placed in the way of recruiting, and who hold that the spending of money by the State upon the food of its soldiers should have as its object the cultivation of health, strength, and contentment in them in the highest attainable degree. So far as the army engaged in fighting is concerned, it appears to be universally agreed that all circumstances being considered the arrangements made for supplying it with food have been admirable.

SKIN AND BODY SCRAPERS.

CERTAIN flint implements of the neolithic age have long been recognised as skin-scrapers, used probably in their day in the dressing of hides and skins. An "acheulite" now lies before us which many years ago belonged to the late Sir Joseph Prestwich. It was picked up by him when in the society of Boucher de Perthes and Sir John Lubbock at St. Acheul, near Amiens, as long ago as April, 1860. In shape it is roughly oval, is about $\frac{1}{2}$ inch in thickness, 2 inches long, and $1\frac{1}{2}$ inches wide. The edges have been chipped to a certain sharpness, and more than one "bulb of percussion" on both its faces prove it to be beyond doubt a flint worked by man. Sir Joseph Prestwich opined that it was held in the hand and used to scrape off hairs from the hides of animals. It is now thought to have been a razor. The question thereupon arises:

Did proto-man ever use such an instrument to scrape off his own body-hair, which must have been very thick and very hot, or, Job-like, to relieve an itching skin? The flint skin-scaper may indeed be the ancestor of the razor or of the body-scratchers which from the days of the potsherd of Job onwards have assumed various shapes—such, for instance, as a hand at the end of a rod—and been used in many lands either to destroy or evict the flea and the pediculus or to assuage the tortures of a surface eruption. Among the ancients the skin-scaper became in one of its forms the strigil, which was used in the routine of the bath, and is represented in the well-known statue by Lysippus of an athlete drawing such an implement over his forearm. The strigil is a curved and grooved metal instrument, which with its handle somewhat resembles a sickle. The ancients employed it to apply oil as well as to remove wet or perspiration from the skin—hence the groove. But it must have been tiresome to use, and was probably only a time-honoured survival from an age before cloths and towels were known, just as now the lecture survives in an age of books and print. There was a time, of course, when the strigil was the only thing possessed by man to dry himself with. This becomes apparent on referring to the fine collection of eoliths lately exhibited in the Museum of the Royal College of Surgeons of England by that indefatigable collector, Mr. Morris, of Lewes. Mr. Morris's graduated collection of early flints, arranged on the analogical principle, contains many specimens which sceptics have roughly refused to consider as in any way man's handiwork. In love with the Garden of Eden theory of the origin of man, many people are ready to maintain that palæontology is all moonshine, and it was surely somewhat in this spirit that the Anthropological Society applauded Mr. Dawson, of Piltown skull fame, when he showed that a bag of starch can, when suitably sat upon, be broken up into all the well-known eolith shapes. Mr. Morris, however, agrees with him, and anyone who has watched the aboriginal flint-workers of Australia or the traditional gun-flint makers of Norfolk at work will be bound to admit that they often break their flints up by throwing a huge lump down and letting nature split out their working material. Those, however, who have collected eoliths for many years and have candidly examined Mr. Morris's collection, will have come to the further conclusion that whole series of flints, found only in certain areas, such, for instance, as Professor Sir Joseph Prestwich's grounds at Darent Hulme on the North Downs, have certain points in common which prove them to be the work of Nature adapted by the hand of man. Such are the body-scrapers or hollow scrapers akin to the foot-scrapers of the Egyptians and the "body-stones" still used by modern savages. In shape these scrapers greatly resemble the cocked hats made out of paper by boys, the under side being usually polished and concave, and one if not both sides bearing traces of a more or less elaborate chipping process. It is probable that proto-man in Southern England was hairy and gorilla-like, that he suffered from heat or even vermin, and that he used body-scrapers to rub himself down. The stones certainly look as if they could have been used for some such purpose, and, though small, they exactly fill the hand. At the present time, according to Ratzel's "History of Mankind," the Tungoses and Samoyeds use more than one curved instrument in the dressing of skins, which owing

to concavity suggest descent from these eolithic shapes. The Eskimos employ curving bones for the same purpose. After being for ages employed on the human skin the skin-scaper possibly came down in the world and turned into a furrier's tool. Thus by analogy the bee-hive house and round tower of the Stone Age in Ireland have become the hen-house in Dingle, and as such are still erected on the bee-hive pattern near Dunmore Head to-day. The bee-hive house, indeed, lingered as the pigsty in Wales when Stoddart drew one of his prettiest illustrations, and we see it still in the round haystack of North Britain. From the medical point of view it is interesting to surmise that our earliest ancestors suffered from hair, heat, and vermin, and that those best survived who scraped and rubbed so well and so often as to have polished whole multitudes of flints.

CAUTERISATION OF ADHESIONS IN AN ARTIFICIAL PNEUMOTHORAX.

ONE of the greatest obstacles to the induction of a complete pneumothorax and the consequent immobilisation of the lung is the presence of pleural adhesions, which are, unfortunately, exceedingly common in advanced pulmonary tuberculosis. Several operations have been devised with a view to securing the more or less complete collapse of the lung, even when it is almost totally adherent to the chest wall. The latest device comes from Sweden, where Dr. H. C. Jacobaeus and Dr. H. Tideström¹ have elaborated a contrivance enabling the operator to see the interior of the pleural cavity while carrying out small operations on the lung. Under local anæsthesia an ordinary sized trocar is passed through the chest wall into the pneumothorax, and through this trocar a thoracoscope of the size of a No. 12 Charrier is introduced. When the pneumothorax is complete the whole of the upper lobe of the lung can be inspected without moving the thoracoscope; and the entire pleural cavity can be examined in this way without moving the instrument much. Dr. Jacobaeus has examined the pleural cavity in this way in about 200 cases without a single accident or great discomfort to the patient. When an adhesion is located, a small trocar is introduced in its neighbourhood, and through it a galvano-cautery is passed, its movements being controlled by the thoracoscope. In two cases the operation did no harm, but was ineffective, presumably because the adhesions were too extensive to be severed in this manner. But in a third case the operation was most successful. The patient was a nurse, aged 22, the whole of whose left lung was diseased. The sputum contained numerous tubercle bacilli, and fever persisted in spite of sanatorium treatment. The left lung was accordingly treated with injections of nitrogen, and its compression was complete except over a cavity, the collapse of which was prevented by a fibrous band passing from the lung to the chest wall. The thoracoscope was introduced through the fourth intercostal space, and the galvano-cautery through the third space in the anterior axillary line. The adhesion was severed in less than a minute, and the lung was then seen to collapse completely. After a few days of slight fever the patient rapidly recovered, and the sputum dwindled till it disappeared altogether. Dr. M. D. Jacobsson² has also succeeded in severing pleural

¹ Hygiea, vol. lxxvi., No. 15.

² Ibid., vol. lxxvi., No. 17.

adhesions with a galvano-cautery, the movements of which he controlled under the X rays, but he admits that the technique elaborated by Dr. Jacobaeus and Dr. Tideström affords greater facilities for this undertaking.

THE BLOOD PICTURE IN MILIARY TUBERCULOSIS: ITS DIAGNOSTIC VALUE.

It has been pointed out by Matthes in the *Medizinische Klinik*, 1912, that in miliary tuberculosis there occur a relative increase of the polymorphonuclear leucocytes and a relative decrease in the percentage of lymphocytes. The total count of white cells may be either normal—that is to say, anything between 5000 and 8000 per cubic millimetre—or less than normal. From Professor Matthes's clinic in Marburg comes a paper by P. Wack, published in the *Deutsches Archiv für Klinische Medizin* (1914, vol. cxv., p. 596), which seems further to confirm this observation. In nine cases of miliary tuberculosis the blood was examined; in all but one of these cases the diagnosis was confirmed ultimately by post-mortem examination. The odd case was a straightforward one of tuberculous peritonitis and miliary tubercles elsewhere. A typical blood count in such a case (Case 7 of the series, for example) shows as follows:—

	Normal.	Miliary tuberculosis.
Leucocytes	5000 to 8000	6400
Polymorphs	70 per cent.	88.5 per cent.
Lymphocytes	25	8.5
Other elements	2 to 5	2.5

In some cases the proportion of polymorphs is not so high, in others it may be extraordinarily high—e.g., 94 per cent. of all white elements (Case 7). It is interesting to note that as the case progresses the excess of polymorphs over lymphocytes increases; this is well shown in Case 1 of P. Wack's series. The patient was under continuous observation for the last seven weeks before her death and the blood was examined 21 times. For the first three weeks of this period the proportion of polymorphs was about 70 per cent., a normal figure, and that of the lymphocytes was about 30 per cent., again fairly normal. Then followed during the last few weeks a progressive change of the blood picture till the typical lymphocytopenia and excess of polymorphs were well marked. Continuous blood examination, a leucocyte count, constitutes, so Naegeli suggests, as delicate an indication of the progress of the case as does the pulse and temperature curve. Lymphocytosis in this relation suggests a more favourable prognosis; excess of polymorphs, on the other hand, is less satisfactory, and may betoken secondary infection. It is of interest to note that the total leucocyte count may be below normal. As regards differential diagnostic value, abdominal typhus may show a marked leucopenia, even to only 1000, but there is relative excess of lymphocytes. Sepsis shows leucocytosis, not usual in miliary tuberculosis. Febrile pulmonary tuberculosis with few focal signs generally gives a lymphocytosis and the neutrophile cells are either normal or only slightly reduced. Finally, a remarkable example of the polymorphonuclear demand which these cases of miliary tuberculosis may provoke is quoted, when the blood picture certainly suggested an acute myelogenous leukaemia, which turned out to be miliary tuberculosis at the post-mortem examination. This case

was interpreted as essentially miliary tuberculosis which had stimulated the marrow to produce the myelogenous unformed elements. A similar case of this character is also noted (Kast) in which there were 32 per cent. of myelocytes. The post mortem examination showed miliary tuberculosis and the marrow indicated no abnormality. This relationship of miliary tuberculosis to such forms of leukaemia is of interest, and the lesser marked blood changes as above noted seem to have a value of some degree, both for diagnosis and, perhaps, for prognosis.

THE OPPORTUNITY FOR WOMEN IN MEDICINE.

THE annual meeting of the New Hospital for Women on March 11th directs particular attention to the fact, which we have already commented upon, that now is an exceptional time for women to adopt a medical career. Among the cataclysmic results of the war is a shortage of doctors necessary to meet the needs not only of the army and navy, but of civil practice, hospital work, the health department, and other non-military public services. Moreover, the shortage in the immediate future is likely to increase rather than to diminish, for not only are many junior students interrupting their curriculum to go to the front in various capacities, but there is also a marked fall in numbers of those entering for a medical career, so that there will necessarily be a corresponding falling off of graduates some six years hence. This future shortage, even more than the present deficiency, forms a powerful justification for an increase in the number of women students of medicine. The proved capabilities of women in this direction are well demonstrated by Professor Howard Marsh,¹ who in an article in the *Cambridge Review* examines the question of what position women have, as a matter of fact, attained in the medical profession and what are their credentials for the practice of medicine. He points out that the entries at the London School of Medicine for Women are progressively increasing, and this year numbered 65, while the number of students now in the school is 220. In examinations women have attained very high distinction, having carried off gold medals in open competition with men in anatomy, physiology, midwifery (three times), surgery, medicine, forensic medicine (twice), and State medicine, in proportion to their relative numbers a very high percentage; and since the Conjoint Examination of the Royal Colleges of Physicians of London and Surgeons of England has been thrown open to them one woman has taken the F.R.C.S. Professor Marsh speaks from his own knowledge of women who display every endowment and qualification necessary for the higher levels of operative surgery and whose results are as favourable as any obtained by men in similar groups of cases, while in general practice and in the various departments of public health their efficiency and success have been conspicuous. Professor Marsh lays particular stress on the administration of anaesthetics as a test of efficiency, and states that out of the 3577 operations performed during the last seven years at the New Hospital for Women, where anaesthetics are invariably given by women only, there have been only two deaths under an anaesthetic, a truly remarkable result. Women are now filling, in a

¹ The Scarcity of Doctors, *Cambridge Review*, Feb. 24th, 1915.

most satisfactory manner, the post of resident medical officer at many provincial hospitals, and it was recently stated that Surgeon-General Sir Alfred Keogh had invited Dr. Flora Murray and Dr. Garrett Anderson, after seeing their work at the front, to come to London and take charge of a new military hospital to contain 500 beds, to be staffed entirely by women, women orderlies working under the sisters. A point that has been a source of great difficulty with regard to the employment of women in other pursuits in competition with men has been a tendency on the part of women to undersell men. It is satisfactory to learn from Professor Marsh that those in authority are taking measures for the prevention of this tendency in medicine. It is understood that when medical men return from military service the medical women who have acted as their substitutes will retire in their favour. This will in some cases constitute hardship, but no other course is possible or desirable. We are glad to feel sure, however, that these women practitioners who have done good work will readily find other openings, in view, not only of the shortage of medical men, but especially because of the enormous development of official medical service that has already taken place, and will probably continue to take place when the war is over.

SENILE PARAPLEGIA.

IN the *Medical Record* of Jan. 30th Professor M. A. Starr has described one of the maladies of old age which has received little attention either in text-books or in other forms of medical literature—senile paraplegia. Under this symptomatic title there appear to be included different pathological conditions, which, however, present a similar clinical picture. Senile paraplegia begins after the age of 65 years, the time depending upon the general vitality of the patient. He gradually becomes more feeble and notices first increasing disability in walking, going up stairs, or standing for any length of time. In the end he becomes bedridden. In some cases the weakness is attended by ataxia, which is more marked than the weakness. In other cases pain is a prominent symptom and is felt either on movement or on standing, although it may occur spontaneously. It is particularly severe after exertion and towards night. The pain is always attended by coldness of the feet and legs and not infrequently by sensations of numbness and tingling. Atrophy of the muscles is more marked than is usual in feeble old persons, and the tendon reflexes are lost. The limbs are usually flabby, cold, and blue, and not infrequently œdema occurs when the patient is out of bed. Occasionally loss of control of the sphincters occurs late in the case. Pain in the back and round the loins is common and may cause insomnia. As a rule the hands and arms are not affected. The cases seem to form three pathological groups: 1. The primary disease lies in the muscles and may be likened to a slowly progressive muscular dystrophy. 2. There is evidently an active degenerative neuritis characterised by spontaneous pain, burning and tingling, and tenderness along the nerves. Areas of hyperæsthesia and anæsthesia in the legs are not uncommon. The anterior crural nerves appear to be more frequently affected than the sciatic, and not infrequently there is considerable pain in the rectum and bladder, showing that all the branches of the sacral plexus are involved in the degeneration.

3. The spinal cord is evidently the seat of disease. There are ataxia and involvement of the sphincters in the early stage. The muscular atrophy appears to be more rapid than in the previous groups, and in the later stages trophic symptoms in the skin are more frequent. Professor Starr suggests that the pathological condition is venous congestion of the lower portion of the spinal cord leading perhaps to œdema. The prognosis in all cases is manifestly unfavourable, but there may be great variations in the course and marked improvement, more or less temporary, under treatment. In the muscular cases a stimulating diet with meat and fatty foods, diminution in the amount of salt taken, and administration of alcohol and small doses of strychnine will cause some arrest of the degeneration and improvement in the symptoms. Warm baths at a temperature of 100° F. for 20 minutes and mild massage are beneficial. But in cases of neuritis baths and massage should be avoided on account of the tenderness, and warmth should be applied by heating the bed. In the spinal cases hot and cold douches to the back, massage of the back and limbs, and dry cupping of the spine are of service. The patient should lie prone so that gravity may aid in emptying the congested veins. Senile paraplegia is easily distinguished from spastic paraplegia due to lateral sclerosis, in which muscular rigidity with exaggerated knee-jerks are present. It should not be confounded with the paraplegic condition of slow onset appearing late in Parkinson's disease, where the tremor is usually a prominent symptom and the gait is slow, shuffling, and stiff, with a tendency to fall.

PROLONGED VACCINE THERAPY IN TYPHOID FEVER.

Professor V. Pensuti publishes in a recent issue of *Il Policlinico* a further series of 69 cases of typhoid fever treated by vaccines. These cases seem to show that vaccine therapy in this disease has an indisputable efficacy, possesses the requirements of a specific treatment, and if in some cases the evidence of its utility has not been immediately apparent later observations on patients, and on the behaviour of the course taken by the infection, render its application more clear and profitable. Having noticed that typhoid patients, whether they recovered naturally or by vaccine treatment, were prone to have relapses, Professor Pensuti took note of the number of relapses occurring in a group of cases vaccinated with a limited number of injections. He found a relapse occurred in about one out of every four. He then had recourse to 31 new cases in which, having vaccinated them with doses believed to be sufficient, he repeated for some time a daily small injection of vaccine and kept them under observation as long as possible after the cessation of fever to notice whether relapses took place. The doses employed were 12,500,000 daily, and in a child aged 5 years and in another aged 7 years 6,000,000. These injections were given for 11 to 25 days and the period of observation lasted for about three weeks. None of these cases had any relapse, although occasionally there were rises of temperature for a period of from four to six hours with a maximum of 37°–38° C. With regard to the effect of the treatment on the duration of the illness, Professor Pensuti records a fair number of cases in which the fever promptly came to an end; the effect on the general condition and

on the various symptoms was none the less marked, while albuminuria diminished and disappeared so rapidly as to render it difficult not to admit a causal connexion between this fact and the vaccination.

THE Lumleian lectures will be delivered at the Royal College of Physicians of London by Dr. Sidney Martin, on Non-ulcerative Infections of the Colon, on March 18th, 23rd, and 25th at 5 P.M.

Sir Almroth Wright will deliver a special lecture before the Royal Society of Medicine on Tuesday, March 30th, at 5 P.M., on the Septic Infection of Wounds, in which he will lay before the profession the results of his investigations and research with the Expeditionary Force.

At a meeting of the Council of the Royal College of Surgeons in Ireland held on March 4th, Mr. F. Conway Dwyer, the President, being in the chair, Dr. Richard Travers Smith was elected to the Professorship of Materia Medica, Therapeutics, and Pharmacy in the Schools of Surgery.

It has been decided that the annual meeting of the British Association for the Advancement of Science shall take place in Manchester in September. Owing to war conditions, however, in place of offering the customary elaborate social hospitality, it is held preferable, while maintaining unbroken the long continuity of yearly meetings, that the proceedings this year should be restricted to the more purely scientific functions.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

AN extraordinary Comitia was held on March 4th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following communications were received:—1. From the Secretary of the Royal College of Surgeons of England, dated Feb. 15th, reporting proceedings of the Council of that College on Feb. 11th. 2. From the secretary of the Charity Commission, dated Feb. 19th, enclosing a scheme for the administration of the charity, to be called "The British Hospital for Mothers and Babies," to the managing committee of which the College consented to send a Representative Member. It was resolved that it should be left to the President to nominate a representative.

RED CROSS WORK IN DEVONSHIRE.—At present there are 21 Red Cross hospitals, which are occupied by wounded soldiers, in the county of Devon.

THE LATE DR. A. F. LEGGE.—Our Aberdeen correspondent writes: "The late Dr. A. F. Legge, who was killed in the recent riot at Singapore, was the son of the late Rev. James Wilson Legge, teacher at the Aberdeen Grammar School. He graduated M.B., Ch.B., at Aberdeen University in 1912, and was for a time house surgeon in the Aberdeen Royal Infirmary, and subsequently house physician at the Aberdeen Royal Asylum. Early last year he went to Singapore to take up duty in the asylum there, and on the outbreak of war volunteered for service with the contingent of the Malay Federated States. When in Aberdeen Dr. Legge was a prominent and popular figure, taking a worthy part in the social and athletic life of the city and university."

MEDICAL PRACTICE AT GILLINGHAM AND CHATHAM.

(FROM OUR SPECIAL COMMISSIONER.)

I HAD two reasons for going to Gillingham to see how the present national conditions affect the well-being of the medical profession. Firstly, Gillingham, though not in the borough, is really an extension of Chatham, and personally concerned in much of the naval and military activity. Next, it may be remembered that Gillingham was one of the principal storm centres in the resistance organised by a large section of the medical profession against the working of the National Insurance Act.¹

Though two years have elapsed since on the occasion of a previous visit I described the attitude of Gillingham doctors towards the National Insurance Act, the practitioners who were opposed to the Act then have remained unchanged in their attitude and still refuse to go on the panel. It was therefore necessary to import medical men to make up the Gillingham panel. But in spite of this addition to their numerical strength the medical practitioners at Gillingham are fully employed, the war circumstances producing this result. Some of them may also find that the increase of their income is not in proportion to the increase of the work they have to do, but that is another question. The medical practitioners of Gillingham have had sufficient forethought not to allow themselves to be placed in the awkward position which I described a week or two ago to have overtaken their colleagues in Great Yarmouth.² The British Medical Association suggested that the medical profession throughout the country should offer to attend gratuitously all the *necessitous* dependents of soldiers who had volunteered for the front. On August 7th, immediately after the declaration of war, at a special meeting of the London Panel Committee, the doctors on the panel were invited to express their willingness to attend, free of charge, *necessitous* dependents of reservists called to arms. This patriotic impulse, however, soon extended without anyone seeing at once whither a heedless generosity might lead. The medical practitioners of the entire kingdom, whether on the panel or not, offered their gratuitous services in this way, and instead of the dependents of the reservists it became the dependents of all those who enlisted. Nobody in those days foresaw the size of our army and no one knew anything for certain about the pay and allowances of the men. And to make the effect of miscalculation worse the word *necessitous* qualifying the dependents was withdrawn. Had that word been maintained no harm would have been done.

Gratuitous Attendance on Recruits.

Doubtless the practitioners of the three towns—Rochester, Chatham, and Gillingham—were better acquainted with the conditions of military and naval service than their London brethren, and indeed than doctors in most of the other parts of the country. In any case, they refused to attend gratuitously all the dependents of soldiers or sailors. They saw no reason why they should thus attend families who had always paid medical fees and were now better off than before the war. Every medical practitioner, panel or not, showed himself most willing to give free and devoted attention to *necessitous* dependents, and a great deal of gratuitous work is being done, but not for the well-to-do families of men who have enlisted.

It was the more necessary to draw the line somewhere as the civil medical practitioners do a great deal of gratuitous work for the army. At Gillingham no less than 10,000 soldiers were billeted on the population or lodged in any building that could be made available for such a purpose. There was no military medical staff attached to this large body of recruits, and they were, of course, liable to the ordinary sickness affecting a population of this description. When one of these recruits falls ill in a private house where he is billeted, and he or the landlord sends for a medical man, a small fee is occasionally forthcoming; but more often it is not. There is no guarantee that the medical attendant will receive anything for the trouble he has taken. Then it sometimes happens that one or more of

¹ THE LANCET, March 22nd, 1913, p. 854.

² THE LANCET, Feb. 13th, 1915, p. 342.

these young men collapse on the parade ground. In that case the nearest practitioner is sent for. Naturally he responds to the call. Yet he is never paid; often he does not receive any thanks for the trouble he has taken. In the military organisation such cases were not foreseen, and no arrangements were made either for the courtesies of professional life or for the payment of fees.

Trade and Mourning.

It may be said, with some measure of confidence, that the medical profession in the three towns is making more than it is losing in consequence of the war. The great influx of recruits naturally brings money, and the people are for the most part not only fully employed, but they are working overtime. On the other hand, many of the ships that have been sunk during the course of the war were commissioned at Chatham. The wives and families of the sailors, whose loss we deplore, live in the three towns. I was told that there were 60 widows in one street. There is every reason to hope this is an exaggeration, but that such a figure should be mentioned illustrates how much this neighbourhood has suffered from the naval disasters. Of course, if a sailor who thus gallantly lost his life had not settled his doctor's bill it is hardly likely his bereaved family will be pressed for payment. In this manner practitioners have experienced some losses, amounting, in one or two cases, to quite a considerable sum. Then there is always a tendency to exploit such situations to the detriment of the medical profession. Thus a sorrowful widow presents herself to a practitioner at Gillingham. Judging by the distress she manifested he at first inferred she had lost her husband in one of the ships recently torpedoed. He was therefore quite disposed to give her his best care gratuitously. But on inquiry he found that, though she undoubtedly was a sailor's widow, her husband died before the war began; that she was in receipt of a pension; that she was in full employment and earning good wages; and finally, that she had two sons, also fully employed, and one of them was in a position to assist her if necessary.

Loss of Time.

Medical practitioners, whether on the panel or not, have also to give a good deal of time to the signing of identification papers. To obtain a separation allowance someone in a good position must testify that the bearer is the person entitled to the money. A clergyman or a doctor is generally selected for that purpose, and as it is better known when the doctor will be found at home most persons appeal to the latter. Again, if the person is ill and cannot go to draw the money, then a medical certificate must be obtained to that effect, so that someone else may receive the money on the patient's behalf. Such applicants not only crowd the waiting room, but sometimes add to the discomfort by bringing with them the children they fear to leave alone. If a real patient calls in the middle of such a scene, and his circumstances permit, he postpones his visit and perhaps forgets to return. Sometimes total strangers will call for a certificate, and are quite surprised because a practitioner does not take them at their word. One case came to my notice of an applicant who wanted a doctor to certify she was the wife of a soldier, so that she might draw her allowance. She had only just come to the town and no one knew her; fortunately she was ultimately able to bring her husband from his regiment to Gillingham and certify she was his wife, and then the doctor signed the certificate. This meant two or three visits paid to the doctor in question and lengthy expostulations and explanations. It implied a good deal more than the professional quarter of an hour, for which no fee was offered or could be claimed.

A continuous pressure is brought to bear upon the medical men also to obtain incorrect certificates. This is especially the case on the part of soldiers who have exceeded their leave and want to prove they were ill. Then there is an idea prevalent that it suffices to be in any way connected with the army or navy to have a right to any medical practitioner's gratuitous services.

Thus it comes about that the war has entailed on the practitioners of Gillingham a good deal of unpaid work and much loss of time. On the other hand, at least in the three towns taken together, there are more money, good wages, and less unemployment, so that a large section of the population should be better able to pay the medical adviser.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet: Francis Julian Richmond Cowie (dated March 2nd) and Alec George Holman (dated March 3rd).

The following appointments have been notified:—Fleet Surgeon (retired): L. Bidwell to the *Marmora*. Surgeon: H. E. R. Stephens to the *Vivid*, additional, for disposal. Temporary Surgeons: W. P. Cowper to the *Vivid*, additional, for Plymouth Hospital; J. Morrison to the *Vivid*, additional, for R.N. Barracks; J. F. Quigley to the *Vivid* and J. Judson to the *Pembroke*, both additional, for disposal; F. J. R. Cowie and A. G. Holman, both to the *Victory*, additional, for disposal; E. I. Parry to the *Roxburgh*; and W. A. Mills to the *Indus*.

ROYAL NAVAL VOLUNTEER RESERVE.

The following appointments have been notified:—Surgeons: W. J. A. Quine to the *Collingwood*; and D. A. Macpherson to the *Vivid* and H. S. Reid to the *Victory*, both additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Major Henry M. Nicholls to be Lieutenant-Colonel (dated March 1st).

The undermentioned to be temporary Captains:—Dated Feb. 15th: Arthur Corrie Keep. Dated Feb. 16th: George Stoker. Dated March 5th: Temporary Lieutenant Arthur Martin Leake, V.C.

The undermentioned to be temporary Lieutenants:—Dated Dec. 1st, 1914: William Bradshaw Davy and John Ferguson Hutton. Dated Feb. 1st: John Anthony Freeman Hatch. Dated Feb. 2nd: George Alexander Shiel. Dated Feb. 3rd: Matthew Hamilton Fleming. Dated Feb. 10th: Frederick Andre Mills, William Tregonwell Collier, and Claude William Scott Saberton. Dated Feb. 11th: Wallace Charles George Ashdowne. Dated Feb. 12th: John Telfer Smeall, Edward Brice Cooper Mayrs, and John Joseph Dunne. Dated Feb. 13th: Harold Arthur Rowell and Ifan Septimus James. Dated Feb. 14th: Richard Desmond Fitzgerald, Louis Laurance McKeever, and Augustine Sargood Fry. Dated Feb. 15th: Reginald Lionel Ernest Downer, Henry Williams Beresford Danaher, Edward Samuel Gooddy, Harold Denny Duke, Carl Frederick Anthonisz, Charles William Donald, Burgess Barnett, John Harold Wrightson, Henry Joseph Milligan, William Richard George Hamilton, Ninian Edward Miles Home-Hay, David Carnegie Alexander, Alexander Jamieson, Ernest Cromwell Peake, Harold Ackroyd, Hugh Watson Fox, Charles Spencer Palmer, Sydney Gordon Tippet, Arthur Ryland Chavasse, George William Davis, Frank Gravely, Gavin Muir, Frank Gardyne Milne, David Anderson Duncan Kennedy, William Harold Butler, John Perry Walker, Thomas Barrington McKee, Meredith Milton Townsend, George Mahony Mayberry, Gerald Davenant Shann, and Frederic Charles Barlow. Dated Feb. 16th: John Kirton, Hayden Peters, William Frank Morgan, Edward Johnson, Robert Condry, Ernest Bosdin Leech, and Ernest Wells Witham.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel C. R. Elliot, R.A.M.C., has been appointed Assistant Director of Medical Services in the 4th (Quetta) Division as a temporary arrangement. Lieutenant-Colonel H. Fooks has been appointed temporary Assistant Director of Medical Services, 6th (Poona) Divisional Area and the Bombay Brigade. Lieutenant-Colonel R. J. Windle, R.A.M.C., has been appointed temporarily to the charge of the Poona Brigade. Lieutenant-Colonel C. H. Hale, R.A.M.C., has been appointed temporary Assistant Director of Medical Services at Abbottabad and Sialkot Brigades. Lieutenant-Colonel S. C. Philson, R.A.M.C., has been appointed temporary Assistant Director of Medical Services, Presidency Brigade. Major M. Corry has been appointed officiating Chief Medical Officer, Delhi Province, with effect from Dec. 1st, 1914. Lieutenant-Colonel F. J. Dewes has been appointed to the Medical Charge of Depot, 28th Punjab, Reserve Centre, 3rd, 21st, and 22nd Mule Cadres, with effect from Nov. 9th, 1914; to the Depot, 27th Punjab, with effect from Nov. 10th; and the Depot, 25th Punjab, with effect from Dec. 23rd, in addition to his own duties. Major L. E. Gilbert has been appointed to the officiating Medical Charge of the 42nd Deoli Regiment and charge of the Cantonment General Hospital, Lahore Cantonment, with effect from Jan. 26th, vice Major D. S. O'Keefe.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Units or Corps: Royal Army Medical Corps.

John Dillon MacCormack to be Lieutenant (on probation). Lieutenant John Brumwell resigns his commission on appointment to the Royal Naval Volunteer Reserve.

TERRITORIAL FORCE.

Army Medical Services.

Lieutenant-Colonel Henry George Falkner, from Attached to Units other than Medical Units, to be Assistant Director of Medical Services, Northumbrian (Reserve) Division, with the rank of Colonel (temporary).

Royal Army Medical Corps.

Yorkshire Mounted Brigade Field Ambulance: Captain John Hepple to be Major (temporary).

2nd East Anglian Field Ambulance: Captain Rees Phillips to be Major (temporary). Frederick George Sharp to be Lieutenant.

3rd West Lancashire Field Ambulance: Walter Richards Stephen to be Lieutenant.

1st London (City of London) Field Ambulance: Lieutenant Martin B. H. Stratford, from Attached to Units other than Medical Units, to be Lieutenant.

3rd London (City of London) Field Ambulance: Lieutenant Robert W. A. Salmond, from 1st (City of London) Field Ambulance, to be Lieutenant.

3rd North Midland Field Ambulance: Thomas Lovett to be Lieutenant.

1st Northumbrian Field Ambulance: Kirton Ivor Seager Smith to be Lieutenant.

3rd West Riding Field Ambulance: John Stratford Hall to be Lieutenant.

1st Welsh Field Ambulance: John Sloan Tomb to be Lieutenant.

1st London (City of London) General Hospital: Lieutenant-Colonel Walter A. Atkinson resigns his commission owing to ill-health, and is granted permission to retain his rank and to wear the prescribed uniform.

1st East Anglian Field Ambulance: Lieutenant Thomas Vicars Oldham, from Attached to Units other than Medical Units, to be Lieutenant.

2nd West Lancashire Field Ambulance: Sydney Sharples (late Lieutenant, 2nd West Lancashire Brigade, Royal Field Artillery) to be Lieutenant.

2nd West Riding Field Ambulance: Benjamin Holroyd to be Lieutenant.

1st Eastern General Hospital: The undermentioned to be Captains, whose services will be available on mobilisation: Wilson Tyson and William Burton Marshall.

3rd Southern General Hospital: Robert Garner Lynam to be Captain, whose services will be available on mobilisation.

1st Northern General Hospital: Major William G. Richardson to be Lieutenant-Colonel. Captain Daniel W. Patterson to be Major.

Eastern Mounted Brigade Field Ambulance: James Lamberton to be Lieutenant.

1st Home Counties Field Ambulance: Richard Austin Freeman to be Lieutenant.

3rd Home Counties Field Ambulance: Captain Edwin A. Houchin to be Major (temporary).

1st East Lancashire Field Ambulance: Transport Officer and Honorary Captain George R. Wattleworth is granted the honorary rank of Major. To be Lieutenants: John Bruce (late Surgeon-Captain, 3rd Volunteer Battalion, The Lincolnshire Regiment) and William Lonsdale Cockcroft.

4th London General Hospital: To be Lieutenants: Arthur Fitzwilliam Comyn and George Arthur Ewart.

1st Scottish General Hospital: The undermentioned to be Captains, whose services will be available on mobilisation: John Taylor and Thomas Hood Wilson Alexander.

Sanitary Service: Major Peter Caldwell Smith to be Lieutenant-Colonel.

Attached to Units other than Medical Units.—Captain David R. Taylor to be Major. To be Captains: John Murdoch (late Captain, 7th Battalion Princess Louise's (Argyll and Sutherland Highlanders) and Lieutenant Arthur E. Ridsdale. To be Lieutenants: Lieutenant Alfred Errol Delgado, from 1st East Anglian Field Ambulance; Charles Joshua Fox (late Lieutenant, 13th (County of London) Princess Louise's Kensington Battalion, The London Regiment); and William Horton Dale.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Major William Owen Evans, attached to Units other than Medical Units, resigns his commission on account of ill-health, and is granted permission to retain his rank and wear the prescribed uniform.

Captain William J. Foster, from the 3rd Southern General Hospital, to be Captain.

DEATHS IN THE SERVICES.

The death of Dr. Frederick Laing Norris, late chief Government medical officer, Antigua, British West Indies, is announced.

Major C. E. Fleming, R.A.M.C., on March 2nd, in his 41st year. During the South African War he volunteered

as a civil surgeon and subsequently received a commission in the Royal Army Medical Corps. He was promoted Captain in 1903 and Major in 1912. In the South African War he took part in the operations in the Transvaal (Queen's medal with four clasps, and King's medal with two clasps).

THE INDIAN AMBULANCE GAZETTE.

It is interesting and eminently satisfactory to note that in spite of the numerous appeals for war and relief funds by other societies the Indian St. John Ambulance Association has supplied in the short period of three months gifts to hospitals representing 2½ lakhs of rupees (or £10,000), while it has organised many voluntary aid detachments, and been active in other directions for the benefit of the sick and wounded. The January issue of the *Gazette* contains much interesting matter, including an account of the Origin and Development of the Red Cross; a lecture on the Laws and Customs of War, so far as they relate to the Sick and Wounded, by Major W. H. M. Spiller, R.A.M.C.; and a thoughtful address by Major-General May, C.B., C.M.G., on the Progress of the War.

RETIRED NAVAL SURGEONS.

In a recent number of the *Military Surgeon* (Chicago, U.S.A.) there is an interesting article by Surgeon (Fleet-Surgeon, that is) C. J. Decker, U.S. Navy, retired, on the employments suitable for medical officers who have retired. The problem introduced has solved itself for this country for the time being, the war demanding the help of all, but Surgeon Decker's views are none the less worth recording for future use. He holds that retired medical officers must find work or "feel lost and stay lost." He strongly dissuades retired officers from trying to become superintendents of civil hospitals, a line of work which in the United States is rapidly becoming a separate profession, and which in this country is becoming more organised and special. As for himself, he joined a large electrical firm and is concerned in elaborate experiments aiming to sterilise by the X rays the ova of beetles in tobacco and cereals as a commercial proposition. Further, he is working on a scheme for instantly killing gonococci by touching them with ultra-violet light (the difficulty seems to be to get the ultra-violet light to the gonococcus), and he has learned how to destroy the life of bacteria and certain other cells by high-frequency currents. The gist of the advice given is that the retired naval medical officer should turn towards scientific research for employment, but the conditions in the United States are obviously more favourable for such an employment of his talents than they would be in this country under existing conditions. The research energies of a man no longer young, who has not been in touch with the actual scientific work of any school for a long time, and has had but rare opportunities of acquiring new laboratory experience or perfecting his bench technique, would not find many outlets or command much remuneration. The career is far the most valuable, suitable, and agreeable one that could fall to the retired naval surgeon's lot, but it would require, save in special instances, a great deal of labour on his part to command success at it.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 9024 births and 7040 deaths were registered during the week ended Saturday, March 6th. The annual rate of mortality in these towns, which had been 18.9, 20.7, and 20.4 per 1000 in the three preceding weeks, further fell in the week under notice to 20.2 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 19.5, against a corresponding rate of 20.2 per 1000 in London. The annual death-rate last week ranged from 9.6 in Wimbledon, 10.3 in Edmonton, 10.6 in Hornsey, 12.5 in Leyton, and 13.1 in Southend-on-Sea, to 23.3 in West Hartlepool, 30.2 in Halifax, 30.7 in Cambridge and in Darlington, 31.2 in Bath, and 34.3 in Stockton-on-Tees.

The 7040 deaths from all causes were 49 fewer than the number recorded in the previous week, and included 618 which were referred to the principal epidemic diseases, against numbers increasing from 511 to 617 in the three preceding weeks. Of these 618 deaths, 331 resulted from measles, 110 from whooping-cough, 71 from infantile diarrhoeal diseases, 64 from diphtheria, 32 from scarlet fever, and 10 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.8 per 1000, and coincided with that recorded in the previous week. The deaths attributed to measles, which

had been 207, 263, and 306 in the three preceding weeks, further rose to 331 last week, and caused the highest annual death-rates of 3.1 in Tottenham, 3.2 in West Hartlepool, 3.3 in Salford, 3.6 in St. Helens, 3.8 in Wolverhampton, 3.9 in Gateshead, 4.0 in Rotherham, 4.4 in Darlington and in Stockton-on-Tees, 5.7 in Northampton, and 7.2 in Cambridge. The deaths referred to whooping-cough, which had been 125, 135, and 111 in the three preceding weeks, were 110 last week; the highest death-rates from this disease were 1.2 in Brighton, in Reading, in Blackburn, and in Merthyr Tydfil, 1.5 in Bath, 1.6 in St. Helens, 2.0 in Aberdare, 2.1 in Bootle, and 2.2 in Ealing. The fatal cases of diarrhoea and enteritis (among infants under 2 years), which had been 70, 80, and 75 in the three preceding weeks, further fell to 71 last week, and included 16 in London, 6 in Liverpool, and 5 in Birmingham. The deaths attributed to diphtheria, which had been 66, 80, and 72 in the three preceding weeks, further declined to 64 last week, of which 16 occurred in London, 8 in Manchester, 5 in Liverpool, and 3 each in Stoke-on-Trent and Birmingham. The deaths referred to scarlet fever, which had increased from 22 to 38 in the four preceding weeks, fell to 32 last week; 7 deaths were registered in London, 4 in Birmingham, 3 each in Manchester and Newcastle-on-Tyne, and 2 each in Tottenham and Nottingham. The fatal cases of enteric fever, which had been 16, 17, and 13 in the three preceding weeks, further fell to 10 last week, and included 3 in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3041 in the 14 preceding weeks, had further decreased to 2943 on Saturday last; 298 new cases were admitted during the week, against 368, 295, and 302 in the three preceding weeks. These hospitals also contained on Saturday last 1569 cases of diphtheria, 240 of measles, 63 of enteric fever, 15 of whooping-cough, and 5 of small-pox. The 1781 deaths from all causes in London were 51 fewer than in the previous week, and corresponded to an annual death-rate of 20.6 per 1000. The deaths referred to diseases of the respiratory system, which had been 455, 459, and 476 in the three preceding weeks, fell to 468 in the week under notice, but were 208 above the number registered in the corresponding week of last year. The deaths from influenza numbered 48, against numbers rising from 44 to 83 in the four preceding weeks.

Of the 7040 deaths from all causes in the 96 towns 197 resulted from different forms of violence and 512 were the subject of coroners' inquests, while 1929 occurred in public institutions. The causes of 81, or 1.2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Bristol, Bradford, Portsmouth, Salford, and in 44 other smaller towns. Of the 81 uncertified causes, 16 were registered in Liverpool, 13 in Birmingham, 5 in Preston, 4 each in Stoke-on-Trent and Darlington, and 3 each in St. Helens, Rochdale, and Blackpool.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1236 births and 1043 deaths were registered during the week ended Saturday, March 6th. The annual rate of mortality in these towns, which had declined from 24.1 to 21.2 per 1000 in the four preceding weeks, rose to 23.2 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 22.9, against 19.5 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 12.9 in Clydebank, 14.7 in Perth, and 15.3 in Kirkcaldy, to 27.4 in Greenock, 33.4 in Falkirk, and 40.6 in Dundee.

The 1043 deaths from all causes were 87 in excess of the number in the previous week, and included 145 which were referred to the principal epidemic diseases, against 139 and 131 in the two preceding weeks. Of these 145 deaths, 91 resulted from whooping-cough, 21 from measles, 15 from diphtheria, 9 from scarlet fever, 7 from infantile diarrhoeal diseases, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3.2, against 1.8 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 81, 97, and 89 in the three preceding weeks, rose to 91 last week, and included 47 in Glasgow, 25 in Dundee, 8 in Edinburgh, and 3 in Greenock. The deaths referred to measles, which had been 11, 13, and 8 in the three preceding weeks, rose to 21 last week, of which 10 occurred in Glasgow and 9 in Dundee. The fatal cases of diphtheria, which had been 6, 8, and 11 in the three preceding weeks, further rose to 15 last week, and included 6 in Glasgow, 5 in Edinburgh,

and 2 in Aberdeen. The deaths attributed to scarlet fever, which had been 8, 10, and 11 in the three preceding weeks, fell to 9 last week; 4 deaths were recorded in Glasgow and 2 in Clydebank. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had declined from 16 to 10 in the four preceding weeks, further fell to 7 last week, and comprised 2 each in Glasgow, Edinburgh, and Aberdeen, and 1 in Dundee. The 2 fatal cases of enteric fever belonged to Glasgow.

The deaths referred to diseases of the respiratory system, which had declined from 302 to 235 in the four preceding weeks, rose to 264 in the week under notice, and were 138 in excess of the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 34, against 26 and 34 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 663 births and 636 deaths were registered during the week ended Saturday, March 6th. The annual rate of mortality in these towns, which had increased from 24.0 to 27.6 per 1000 in the six preceding weeks, fell to 27.4 per 1000 in the week under notice. During the first nine weeks of the current quarter the mean annual death-rate in these towns averaged 26.0, against corresponding rates of 19.5 and 22.9 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 33.4 in Dublin (against 20.6 in London and 21.8 in Glasgow), 26.9 in Belfast, 26.5 in Cork, 20.2 in Londonderry, 20.3 in Limerick, and 22.8 in Waterford, while in the 21 smaller towns the mean rate was 20.2 per 1000.

The 636 deaths from all causes were 6 fewer than the number in the previous week, and included 36 which were referred to the principal epidemic diseases, against 36 and 38 in the two preceding weeks. Of these 36 deaths, 11 resulted from infantile diarrhoeal diseases, 10 from whooping-cough, 8 from measles, 4 from scarlet fever, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.5, against corresponding rates of 1.8 and 3.2 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 13, 10, and 5 in the three preceding weeks, rose to 11 last week, and comprised 10 in Dublin and 1 in Belfast. The deaths referred to whooping-cough, which had been 17, 12, and 18 in the three preceding weeks, fell to 10 last week, of which 6 were recorded in Dublin, 3 in Belfast, and 1 in Larnie. The fatal cases of measles, which had been 5, 6, and 8 in the three preceding weeks, were again 8 last week, and comprised 5 in Belfast, 2 in Portadown, and 1 in Dublin. The 4 deaths attributed to scarlet fever, of which 3 belonged to Belfast, were equal to the average in the earlier weeks of the quarter. The 2 deaths from diphtheria were recorded in Dublin and Belfast respectively, and the fatal case of enteric fever in Belfast.

The deaths referred to diseases of the respiratory system, which had been 182, 168, and 187 in the three preceding weeks, were 188 in the week under notice. Of the 636 deaths from all causes, 190, or 30 per cent., occurred in public institutions, and 7 resulted from different forms of violence. The causes of 26, or 4.1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 1.2 per cent.

MEAT INSPECTION IN DEVONSHIRE.—The medical officer of health of the Torrington rural district, in his annual report for 1913, refers to the fact that at present there is no systematic inspection of meat in the district, and adds that in the few districts where a regular system of such inspection obtains evidence is found that a considerable amount of unsound flesh is put on the market month after month.

BRISTOL ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual meeting of the subscribers of this institution was held on March 2nd. The medical report stated that during 1913 the in-patients numbered 1121 children and 109 women; 3729 children and 1316 women were treated in the out-patient department, and 843 patients in the dental department. The financial statement showed the income amounted to £4714, and there was an unfavourable balance of £850. £2000 was recently bequeathed to the charity by the late Lady Greville Smith, to whom the hospital also owes the block of isolation buildings.

THE PROPHYLACTIC TREATMENT OF
PUERPERAL INFECTION BY DILUTE
SULPHURIC ACID.

To the Editor of THE LANCET.

SIR,—It has afforded us much pleasure to read in a letter by Dr. J. L. Moir in your issue of Jan. 16th of the favourable results he has obtained by the dilute sulphuric acid treatment in the prophylaxis of puerperal infection, because they still further afford evidence of the real value of this remedy in pyogenic infections. The subject of puerperal infection is such an important one that the extension of this mode of treatment as a prophylactic measure should be a valuable step forward.

We now draw special attention to the alteration in strength of acid sulphuric. dil. as the official preparation in the new Pharmacopœia, 1914, because the strength has been reduced by 26·7 per cent. It thus becomes necessary to point out that the dose in this treatment must be materially increased to be equivalent to the 20–30 minim doses of the acid sulphuric. dil. of the old Pharmacopœia. The dose should now be 25–35 minims. We cannot help feeling that great benefit might be derived by the administration of this remedy to the wounded in the present European War, as many of the infected wounds would, we believe, run a much more favourable course; indeed, it would be better if the treatment were adopted as a routine prophylactic measure. Sulphuric acid is so inexpensive, and so easily obtained, that even for such an extensive use the question of expense is negligible, and it has the additional advantage of acting as a direct tonic. Dr. Moir also raises an interesting point when he speaks of its effect in increasing the resisting power of the tissues to infection. This view seems to be borne out by experiments already conducted, but the question as to whether diminution of the alkalinity of the blood is responsible for the increase of the resisting power yet remains to be decided. The experimental work involved in the investigation of this subject is necessarily long and tedious and is still being conducted.

We are, Sir, yours faithfully,

J. REYNOLDS.

London, S.W., March 8th, 1915. RUSSELL J. REYNOLDS.

OPEN-AIR TREATMENT OF ACUTE
SPECIFIC FEVERS.

To the Editor of THE LANCET.

SIR,—With regard to the open-air treatment of measles and Mr. J. Tertius Clarke's letter in THE LANCET of March 6th, I should like to bear my testimony to the effect of ventilation and light in diminishing the mortality of this disease. In Woolwich the death-rate from measles between 1891 and 1900 was 0·59. During the past four years it has been reduced to 0·19, or about one-third of what it formerly was. There is no question here of diminished prevalence, although if the death-rate was calculated on the number of children living at ages 0 to 5 the fall would not be so great as it appears, but even then it would be very considerable.

About the year 1900–01 the practice was commenced of distributing at all houses where cases of measles were notified by school teachers instructions as to keeping the windows open and blinds up, and keeping the child clean. To the adoption of these instructions I mainly attribute the fall of mortality. No doubt if more thorough open-air treatment was adopted the mortality might be still further reduced.—I am, Sir, yours faithfully,

SIDNEY DAVIES,

Medical Officer of Health.

Public Health Department, Woolwich, March 8th, 1915.

A GRIEVANCE.

To the Editor of THE LANCET.

SIR,—Most of the Insurance Committees throughout England are only paying 1s. a head on account for last quarter owing to the action of the Insurance Commissioners in preventing the societies sending lists of those members who have joined the army or navy to the committees concerned. This has resulted in a great many panel doctors being placed in very awkward financial straits at a time when credit is almost impossible to obtain and when many of us who have been called up were counting on the money thus held up to pay our substitutes. It is preposterous to suggest that even a quarter of the 8d. in addition to the 4d. already withheld will be necessary to balance the removals from our lists.

Now another grumble at the action of the War Office in paying officers with temporary commissions several shillings a day more than Special Reservists and Territorials who have taken the trouble to qualify for commissions in times of peace, who, moreover, have established practices and homes to keep up, whereas very many of the temporaries are young men with no responsibilities whatever. I know it will be said we did it with our eyes open. But we did not bargain for the War Office collaring practically three-quarters of the men we were looking to to fill our places when we were called up and thus making locums so expensive and unobtainable that in my own case I have had to pay £150 a year more than I get as army pay. Goodness knows, I do not wish to grumble, but I feel that I am voicing the opinion of practically all Reservist and Territorial medical officers.

I enclose my card and wish to remain,

Yours faithfully,

ANONYME.

THE SHORTAGE OF LOCUM-TENENTS AND
RESIDENT MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—I may start with remarking that I have nothing to say against any medical agent or the secretary of any hospital. I have dealt once only with each of them respectively, and the agent kindly reduced his fees by one-half on my asking for consideration in special circumstances, and this although he had my signature to his full terms. The secretary to the hospital made my life there as comfortable as it possibly could be. I am a middle-aged practitioner now, and I remember both men with gratitude. I would like, however, to make a few remarks on what occurs outside the sphere of the agent or hospital secretary. The main reason for going into a hospital is to be taught. In many cases the staff are too busy to teach much, and valuable time is wasted. The agents are business men and quite fairly and at a

moderate commission cater to provide assistants or locum-tenents drawn largely from the impecunious members of the profession, in many cases too poor to buy or start a practice. This is the beginning (and it may be the end) of a man's professional life, and may in favourable circumstances (for them) like the present unfortunate war command an income of £5 or £6 a week. At other times if under, say, 45 a sum of £4 may be earned weekly. An oldish man is not wanted, and indeed could not stand the strain of a "farmed-out" practice. Unless the newspapers are lying grossly these sums are the wages of good artisans in each case, and that for say an eight or ten hours day. Another service which is grumbling is the asylum. Now it was well known in every medical school that suitable men were harder to find for that than any other service. Tempting salaries were offered to juniors to accept the minor posts and they found perhaps after a dozen years of waiting they were £70 or £100 a year better off. They had to live in some cases under Prussian discipline, were prohibited from marriage, cut off from all the social amenities of life unless in the rare instances where they became superintendents. Their condition then changed from servility to that of an autocrat in their own institution. Will any man in his senses educate a son at, say, an outlay of £1000 for a life like this? I think that sum might be much more advantageously employed in other ways, and so think many parents.

Feb. 27th, 1915.

I am, Sir, yours faithfully,

A. B. C.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Local Government Board and the Longford County Infirmary.

THE Local Government Board has communicated to the governors of the Longford County Infirmary its decision in regard to the proposal of the governors to dismiss Mr. Mayne, surgeon to the infirmary, for his action in refusing permission to another surgeon to operate in the infirmary. The Board refuses its assent to the dismissal of Mr. Mayne, who "acted within his discretionary powers under Article 11 of the Rules and Regulations of the County Infirmary."

Professorship of Materia Medica.

The President, Vice-President, and Council of the Royal College of Surgeons in Ireland have elected Dr. R. Travers Smith, F.R.C.P. Irel., to the chair of Materia Medica, Therapeutics, and Pharmacology in the School of the College.

"Medical Certifiers" and the Irish Medical Profession.

The recent appointment by the Insurance Commissioners of a number of "medical certifiers" is rousing bitter opposition in the medical profession in all parts of Ireland. A meeting of the medical men of Cork decided unanimously that all practitioners of the city should be called on to bind themselves to refuse to meet any certifier. Similar action has been taken in Co. Wexford, Co. Tyrone, and other districts. In Co. Cavan the position has been somewhat anomalous. The Commissioners induced some six practitioners of the county to accept posts as certifiers. A meeting of the local medical committee was

summoned to consider their action. Owing to short notice and very severe weather only 11 members attended the committee. The six certifiers thus formed a majority and passed a resolution approving of their own conduct. All the other practitioners in the county—some 21 in number—have since formally repudiated the action of the committee, and demanded the abolition of the system of whole- or part-time certifiers.

The Belfast Literary Society.

Sir John Byers has been elected President of the Belfast Literary Society for 1915-16, a position he held before in the year 1885-86. It is one of the oldest institutions in Belfast, having been founded in 1801.

March 9th.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

DURING the week the Fund has progressed well, and it will be seen by the statement of subscriptions that substantial contributions have been received from Canada and from Denmark. The Danish Union of Doctors has sent through Dr. Christophersen a second handsome subscription to the Fund of Kr.3488, equivalent to £178 8s. 3d. We shall publish a detailed list of the subscriptions in a later issue. The Canadian Committee for the Relief of the Belgian Medical and Pharmaceutical Professions forwards through Dr. J. Gibb Wishart, the President of the Ontario Medical Association, a further donation of \$1000. The previous two generous contributions of this Committee, amounting to over £300, were credited to the Ontario Medical Association in error.

We publish this week a fourth list of subscriptions to the Fund which have been received by the treasurers of the Irish Branch, and a detailed list of the Scottish subscribers. When these large collections, and other subscriptions still remaining in the hands of local secretaries, are added to what has been received by the treasurer, Dr. Des Vœux, the total Fund will amount now to more than £10,000.

Distribution has proceeded regularly, and the applicants for assistance have shown themselves, personally or through Dr. Clément Philippe, very appreciative of the help rendered. The distribution of clothes now takes place from the Wesleyan Training College, 130, Horseferry-road, London, S.W., where Mrs. Leonard Colebrook, Mrs. de Bless, and Count Dru are rendering every help.

THE SCOTTISH FUND.

The following are the subscriptions making up a total of £888 5s. 6d. already in the hands of Dr. R. Cranston Low, Dr. Walker Downie, and Mr. J. Rutherford Hill, the treasurers and secretaries of this fund:—

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd. £7500 had passed into the treasurer's hands by Tuesday last, the sum not including the Scottish and Irish and several large local funds.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Dr. F. Miller Wilson, Liverpool; Dr. F. Fowler, Bournemouth; Dr. C. D. Parfitt, Ontario, Canada; Dr. Priestley Leech, Halifax, Yorks; and Mrs. H. Barton, Market Rason.

A CENTENARIAN.—Mr. John Shintall, of Portarlington, Queen's County, who saw the famous fight between Donnelly and Cooper at the Curragh of Kildare in 1818, has died at the age of 110 years.

SANATORIUM BENEFIT IN IRELAND.—It has long been evident that the funds at the disposal of the Insurance Committees in Ireland are insufficient to meet the demands of the claimants for sanatorium benefit. In some cases the deficiency has been made up by the local authority, but in others, as in the Dublin county borough, the Insurance Committees and the local authorities have failed to come to an agreement. Last year Mr. Lloyd George promised to find further funds to enable insurance committees to meet their full responsibilities, but so far without result. The Dublin Insurance Committee has had temporarily to refuse all applications for the benefit, and it has been decided to treat in future only cases that present a prospect of recovery or improvement, and to discharge from treatment cases not progressing satisfactorily. Clearly, unless some remedy for the difficulty is found the sanatorium benefit must fail.

The War.

THE NEED OF THE ARMY FOR MEDICAL OFFICERS.

THE following letter has been received from the Director-General of the Army Medical Service:—

War Office, Whitehall, S.W.

SIR,—I should be glad if you would allow me to explain through your columns our position with regard to the employment of medical men for the army. It is briefly as follows:—

1. The need of medical men, both for home and foreign service, is acute. We want every qualified man who is physically fit and willing to serve.

2. We are in special need of general practitioners, but would be glad to take on expert surgeons, ophthalmologists, radiographers, &c.

3. We could give suitable men immediate employment.

4. At present we are not, except in special cases, sending men over 40 years of age overseas, but we should gladly take on older men for home service.

5. We do not wish to denude the country of civil practitioners, but every man who can arrange for his work to be done at home should come forward as early as possible if we are to keep up an adequate supply of medical attendance to our armies in the field. This is really a national emergency, and we hope that the medical profession, who have already done so much, will assist the responsible authorities to meet it.

Should any qualified man wish to obtain a temporary commission in the Royal Army Medical Corps he should apply to the Secretary, War Office, Whitehall, S.W., for the necessary forms.

Yours faithfully,

ALFRED KEOGH,

March 10th, 1915.

Director-General, Army Medical Service.

THE HONOURS LIST.

Lieutenant Eric Christian Lang, Royal Army Medical Corps, attached to the 1st Battalion the Leicestershire Regiment, has been appointed D.S.O. for conspicuous gallantry and devotion to duty on two occasions, especially on Feb. 9th, 1915, at Rue Du Bois, when he rescued a severely wounded officer under very difficult circumstances whilst in full view of the enemy.

THE CASUALTY LIST.

The casualties among officers in the Expeditionary Force reported since our last issue include the names of Lieutenant P. M. J. Power, R.A.M.C., and Major F. G. Richards, R.A.M.C., killed; and Captain J. H. Bell, R.A.M.C., Lieutenant T. W. Clarke, R.A.M.C., and Lieutenant C. M. Row, R.A.M.C., wounded.

ANTITYPHOID INOCULATION.

The War Office has published a table showing the distribution of typhoid fever cases among British soldiers in the field among the uninoculated, the fully inoculated, and the partially protected. Among the uninoculated there were 359 cases with 48 deaths (death-rate 13·37 per cent.); among those fully inoculated within two years (two doses), 111 cases with 1 death (death-rate 0·9 per cent.); and among the partially protected (one dose), 136 cases with 1 death (death-rate 0·73 per cent.).

BRITISH RED CROSS SOCIETY.—The summary of the work done during the week ending March 6th shows the number of auxiliary home hospitals accepted by the War Office to date to be 807, containing beds for 22,324, including 344 beds accepted during the past week. At the Netley Red Cross Hospital a total of 452 patients are under treatment. The Good Hope Red Cross Society has up to date met all reasonable demands made upon it by the Director of Medical Services, the principal medical officers of base and stationary hospitals, and the officers commanding field hospitals, &c. On more than one occasion it has been able to meet emergency calls, notably that of the Touws river railway accident, when it despatched a doctor, nurses, and orderlies within an hour from the receipt of the call for assistance. It has also supplied quantities of bed linen and medical comforts to various hospitals to meet sudden demands.

Three motor ambulances have been supplied, for use principally at the base, and there have further been despatched during the week: To Boulogne, 3 ambulances, 2 touring cars, 1 lorry, 2 soup kitchens, and 1 motor cycle; to Dunkirk, 1 ambulance and 1 repair wagon; to Havre, 1 ambulance and 1 cabriolet; to Wimereux, 1 touring car; and to places in England, 2 ambulances.

864 cases of stores were despatched abroad. Of these, 303 were sent to Boulogne and 520 to Calais. The balance represents small amounts sent to other places in France.

117 hospitals in this country were supplied in all with 222 cases of requisites and comforts. The total expenditure upon stores during the week was £1897.

RUSSIA'S SURGICAL INSTRUMENTS PROBLEM.—A Russian correspondent writes: "The problem of the supply of surgical instruments, since importation has become so difficult owing to the war, is being partly solved by the Russian cottage or home industrialists, particularly in the village of Pavloff, in the Nizhegorod government. It appears that the peasant workers there have delivered various surgical instruments of such quality as to convince local traders that not only German, but foreign goods generally of the kind, can now be dispensed with. One large Moscow house that specialises in these goods is establishing a workshop of its own at Pavloff, and is opening there a bureau for giving cash advances to peasants who have devoted special attention to the making of surgical instruments. Instruments received from Sweden are of high quality, but expensive. In a note from Moscow V. N. Rozanoff, the senior surgeon of the Soldatenkoff Hospital, states that he has received from Japan a parcel of surgical instruments of excellent quality. He is expecting similar consignments from England *via* Copenhagen."

A RUSSIAN SURGEON'S WORK AT THE FRONT.

Another Russian correspondent sends us the following translation from the *Novoe Vremya* of Feb. 11th of a letter written by a Russian professor of surgery to his wife, giving details of his work at the front and showing the wonderful fortitude on the part of wounded Russian soldiers and the whole-hearted devotion to duty of the Russian army doctors. "To-day," he says, "I had to operate on an ensign-bearer who was wounded in the brain and who suffered from paralysis in his left arm. Scarcely had I finished that operation when another, of which I shall give you some details, claimed my attention. This is the case of Paul Ivanovitch Semenov, wounded in the jaw and tongue by a German machine-gun. I shall give you a short history of his wound, so that you may, without mentioning my name, tell in the press the following facts of wonderful bravery, endurance, patience, and self-control on the part of a Russian soldier. During my 15 years of medical experience I have witnessed a great deal of patience and endurance, but never, by a long way, to the extent shown in this case. When in the course of an attack Semenov was wounded in the jaw and the root of his tongue by a German machine-gun, his mouth was filled with blood, which nearly choked him. While the battle was still in progress he returned towards his trench, where, seeing a soldier, he asked him for help, as he was very weak from loss of blood. This soldier, a German, turned upon Semenov, caught him by the throat with one hand

and was about to bayonet him with the other. But Semenov, though bleeding profusely and choking with the effusion from his mouth, was not disconcerted; he grappled with the enemy and with the aid of other Russian soldiers who hurried to his rescue made an end of the German.

During the four days which it took him to reach the hospital Semenov suffered from repeated effusions of blood from the mouth. In the morning of the same day that he arrived I extracted, without an anæsthetic, the bullet. Semenov did not utter a sound. Thinking that after the extraction of the bullet the bleeding would stop, I did nothing more than prescribe a mouth-wash. But I ordered the doctor on duty to call me immediately should the bleeding start again. The whole of the day following the operation, which relieved Semenov from excruciating pain, was passed very comfortably. Semenov brightened up, regained his appetite, began talking, and told me how he was wounded. At midnight the doctor in charge summoned me by telephone and told me that Semenov was again bleeding severely. On arriving at the hospital I found the unfortunate man spitting blood in the spittoon, which was nearly full of it. I took him immediately into the operating-room. It was very difficult to insert a suture, the injury being at the root of the tongue. Moreover, as the patient was wounded in the chin and could not therefore open his mouth wide enough manipulation inside the mouth with needle and silk was almost impossible. I therefore determined to stop the bleeding with a red hot iron. It was impossible to administer chloroform; he would have been choked with blood. The other doctor drew out with forceps Semenov's tongue and under great difficulties I began to cauterise that highly sensitive part with a red-hot iron. Not a single groan, not the slightest sound did he utter. I was in tears. But imagine my horror when I found that the red-hot iron did not stop the bleeding, but, on the contrary, increased it. The suture remained the only hope. I do not know whether it was my skill or God's mercy upon the suffering Semenov that brought the operation to a successful end. With intermissions, during which Semenov bled profusely, the medical officer on duty, Kovalsky de Schmiden, a recent graduate, now let go Semenov's tongue, now drew it out again, so that at last I inserted the suture in the mouth and the bleeding stopped. All the time Semenov did not make a moan. When I had finished he only said, 'Well, it has stopped now.' I then noticed that my young colleague was as white as a sheet and was hardly able to keep on his legs. Another moment and he would have fallen. I led him to the window, held him up, and helped him to recover. I do not wonder that these great efforts to save a life had affected him so much.

For the first time in my life I became convinced that I had iron nerves and that I was born to be a surgeon. Semenov astounded me. I bowed to his power of endurance. I respected his trust in me, his firm belief that I would surely save his life. This confidence of Semenov, which did not waver before the red hot iron or the suturing up of his tongue, afforded me much happiness of the rarest kind. The following day Semenov walked about, smoked, conversed, and thanked me, while on his tongue lay the suture of silken thread. Tomorrow I shall remove that suture. Semenov so greatly impressed and touched my soul to its very depth that I could not rest till I had gone up to him and said: 'Semenov, you have shown yourself such a hero, not only on the battlefield but here in hospital, that I shall inform your commanding officer of your heroic conduct. Tell me his name.' He was highly delighted and thanked me. That very day I wrote officially to the commander and concluded my letter as follows: 'I consider it my duty to report these circumstances to you, and hope that your regiment will be proud of their hero, and that you, colonel, will reward him.'

After Semenov I had to operate on a young wounded volunteer. The bullet had penetrated into the third rib on his left side and wounded the lung. As a result a subcutaneous emphysema had spread over the left side of the whole body. From the wound issued noisily an unceasing stream of blood mixed with a foul-smelling matter. The situation was difficult and terrible. The bandages were drenched in blood; they had been changed four times in a few hours. I cut open the second intercostal space of the left side. Before my eyes I could see beating

the noble Russian heart of a volunteer—a young locksmith. All we doctors saw for the first time through the pericardium how a heart beats. I tamponed the putrefying left lung. The patient was turned and I opened the ninth intercostal space of his left side. Here we discovered that the bullet had passed through the diaphragm, and from there plunged somewhere into the abdomen, grazing on the way a part of the spleen. The wound was tamponed. Two days have passed and he is still alive. We yet hope that he will be victorious in his struggle with death. His name is Glef Afanseyevitch Korzhikov, aged 20. My main ambition at the present moment is to save his life. I dress his wounds twice a day.

The whole of my staff are worn out and very tired. Do not be disappointed if I do not come home to rest for some time, though it is the custom for senior medical officers to do so. There is no cause for uneasiness; I am strong, well, and able to bear it all. I work from six in the morning till far into the night. Since the war started there have passed through my hands 1000 wounded."

IN THE BRIGHTON HOSPITALS.—A local correspondent sends us the following notes of some cases that have been admitted to the various hospitals in Brighton:—

Varicose aneurysm.—A patient was shot through the popliteal space by a rifle bullet. Entry and exit wounds were small and healed quickly. In the popliteal space was a pulsating, expansile swelling in the course of the artery, over which were a thrill and a loud roaring murmur. On compressing the popliteal artery above the swelling pulsation ceased. This condition is said to be not uncommon as the result of simultaneous injury of a neighbouring artery and vein by small-bore bullets, but no previous case has been seen in the Brighton hospitals. The artery is only partly divided during the passage of the bullet. In the popliteal space, where artery and vein are in close connexion and firmly bound together, the usual form of arterio-venous communication is an aneurysmal varix. As to treatment, ligature of the proximal artery is in very many cases followed by gangrene. The best procedure seems to be to wait, giving the leg complete rest, in hope that the swelling will subside. If this fails, as it usually does, ligature of the artery above and below the sac without opening it is the ideal operation.

Wound of the spinal cord.—Patient was shot through the back, the bullet entering the spine on one side at the lumbo-dorsal junction and leaving on the same level on the other. Complete loss of sensation and motion in the legs followed, also paralysis of rectum and bladder, with incontinence of urine and feces. Admitted three months after receipt of wound, much emaciated, especially in the legs, with intermittent pyrexia, cystitis, and a large sacral bedsore. In a French hospital he had had suprapubic cystotomy performed, and the urine constantly dribbled through this wound making him sore and uncomfortable. It is difficult to understand on what grounds this operation should have been carried out. He has improved very much in his general condition, as the result of good nursing, feeding, and rest. Cystitis has been much lessened by washing out the bladder twice daily. Bladder has been kept empty by tying in a catheter in order to allow the suprapubic wound to close, when the catheter will be taken out. Laminectomy has been considered, but as none of the indications laid down by the authorities—i.e., great pain above the paralysed region, or an incomplete or recovering lesion with good evidence of pressure or irritation by displaced bone or the retention of a bullet causing pressure or irritation—are present, the operation would serve no good purpose.

Fracture of the lower jaw on both sides.—A bullet passed through the lower jaw on the right side, cut away front half of tongue, and made its exit through the opposite side of the lower jaw. It is not usual for the tongue to be injured by a bullet, unless accompanied by a more serious lesion. Fractures of the lower and upper jaw have been common, and usually do wonderfully well under quite simple treatment.

Cases of bleeding from the arm some time after the infliction of the injury.—A man whose arm had been pierced by a bullet seemed to be doing well, when a sudden, unexpected and copious issue of blood from the wound occurred and the patient died almost at once, before anything

could be done. In another case in which the main artery, the brachial, was not the vessel at fault hæmorrhage occurred, and was treated by ligature at the bleeding point, but the bleeding recurred and it was therefore necessary to amputate the arm.

Frost-bite.—Among the many cases of this malady admitted the same cause operated in all—namely, standing in wet, sodden, cold, and slushy trenches for many days on end with no opportunity of drying or changing boots and socks. In all instances it was the feet that were affected, and all degrees of frost-bite were encountered, from the most serious (gangrene of the toes and even of the front part of the tarsus) to the least serious (those cases which resembled rather a chilblain of the whole foot). In the latter cases little beyond resting the feet and keeping them warm and massaged was required. They soon got well. But in the worst cases a line of demarcation must be awaited, and then as little as possible of the foot removed. It is surprising how marvellously parts which at first sight seem to be passing into gangrene recover if the surgeon will exercise patience. It is therefore well to be in no hurry to operate.

Wounds of the lung.—In the first case the bullet entered the root of the neck just over the sterno-clavicular joint, passed out at the angle of the scapula of the same side, traversing the lung in its passage. The only evidence of wound of this organ was transient hæmoptysis. This patient has a rather curious symptom, which is by no means uncommon after bullet wound of the lung, and that is dyspnoea on even slight exertion. It is said to be due either to contraction of the scar of the track of the bullet or to adhesions in the pleura. It is a troublesome symptom, often disabling the patient for a long time. In another case the bullet went in at the angle of the twelfth rib and passed out above and external to the nipple. It went through both liver and lung. The patient had all the signs of fluid in the chest, and a needle inserted showed a little fluid. This is now absorbing and the patient doing quite well.

Shrapnel wound of the eyeball; excision.—In this man a small fragment of metal had pierced the upper lid, passed through the sclerotic, and remained embedded at the junction of the iris and ciliary body, tearing the former from its attachment. The piece of shrapnel could be seen lying just behind the aperture in the torn iris. The eye being quite blinded, the eyeball was removed to avert the risk of sympathetic ophthalmia. A suture was passed through each muscle before it was cut. These sutures were tied together, and the conjunctiva was sewn up over the stump thus formed to give greater mobility to the artificial eye to be worn later.

Supposed foot-and-mouth disease.—This patient was admitted from "a town in France" with the following history. He had been in charge of horses at a farm in which there were no other animals at all. Taken ill three weeks ago; had a bad cold, and blisters appeared first on his hands, then in his mouth, then on his feet. This was diagnosed in France as foot-and-mouth disease. On admission he was feeling quite well; had no rise of temperature; the mouth was normal; his hands and feet were covered on the palmar and plantar aspects with very numerous blisters, varying in size from that of a pin's-head to that of a threepenny-piece, and yellow in colour. The diagnosis rested between foot-and-mouth disease and cheiro-pompholyx. On the whole, the majority of those who saw the case inclined to the latter view.

VACANCIES FOR MEDICAL OFFICERS.—The War Office announces that more army medical officers are required. Medical men over 40 years of age will be accepted for service at home, and temporary commissions in the Royal Army Medical Corps will be granted without delay. Applications in writing should be addressed to the Secretary, War Office.—We are informed that medical men with sanitary qualifications and experience are wanted to complete the establishment of officers of the 1st London (City of London) Sanitary Company, R.A.M.C. (T.). The present necessity has been caused by the despatch of drafts overseas, and gentlemen now joining the company may expect to be sent on active service at an early date. Particulars as to pay, allowances, &c., can be obtained from the Officer Commanding at Room B 6, Duke of York's Headquarters, Chelsea, S.W., either by letter or by calling between the hours of 10.30 A.M. and 12.30 P.M. any day.—There are vacancies for three Royal Army Medical Corps

officers in the 2/3rd North Midland Field Ambulance at Luton, Bedfordshire, which is now being rapidly trained for the front, and one of these officers should have a knowledge of, and be used to, horses to undertake the control of transport. There is also a vacancy for an officer holding the D.P.H. qualification to take charge of a sanitary section. Lieutenant-Colonel Lewis W. Pockett, R.A.M.C. (T.), the officer commanding, will be pleased to give applicants full particulars or to interview them personally in London or at Luton.—Medical officers are still urgently required for the 2/1st Highland Mounted Brigade Field Ambulance, R.A.M.C. Full particulars of the duties, pay, &c., will be given to anyone applying to Captain Mowat (officer commanding), Drill Hall, Rose-street, Inverness.

THE WOUNDED AT THE LONDON HOSPITAL.—At a court of governors of the London Hospital held at that institution on March 3rd, Viscount Knutsford, who presided, stated that 2000 British and Belgian soldiers had been treated during the period of the war. Patients who were not badly wounded, after being treated in the hospital, were conveyed in motor-cars to adjacent hospitals, and the treatment given to the civilian population had not been reduced. In referring to the London Hospital Contingent, which was formed with the object of offering its services to the War Office, Viscount Knutsford said that it had been decided not to send the contingent to the front as no young people were available, and the committee desired to conserve all their energies in order to carry out their responsibilities to the Admiralty and the War Office. Reference was also made to the picture which was being painted by Mr. John Lavery, A.R.A., showing the wounded in the wards of the London Hospital.

LIVERPOOL FIELD HOSPITAL.—Four specimen blocks of the Liverpool Field Hospital, which is shortly to go to the front, were on exhibition in Liverpool recently, the exhibition being formally opened by the Lord Mayor. The complete hospital will consist of 24 such blocks and will provide accommodation for 230 patients besides the staff and administration. Upwards of £26,000 have been spent on its equipment and maintenance, and monthly subscriptions amounting to a total of £864 have been promised for its support for periods varying from six months to the entire duration of the war. It was decided to follow out the Territorial idea, so that the staff will consist, besides commandant and quartermaster to be appointed by the War Office, of Lieutenant-Colonel Nathan Raw, R.A.M.C. (T.), Major T. C. Litler Jones, R.A.M.C. (T.), X ray specialists, and 7 other medical officers, with a paymaster, dispenser, matron and assistant matron, 41 sisters, nurses, and wardmaids, and 41 orderlies, all of whom will be from Liverpool.

A DISTINCTIVE SIGN FOR CIVIL HOSPITALS.—By the Hague Convention of 1907 it was decided that in case of bombardment civil hospitals and other public buildings should be spared as much as possible and that they should bear a distinctive sign to be made known to the enemy. The Home Secretary, in reply to a question by the town clerk of Leeds, pointed out that the proper sign for such buildings is to display conspicuously a stiff rectangular panel divided diagonally into two triangular portions, the upper painted black and the lower white. The Red Cross is reserved exclusively for hospitals under naval or military control, or where special authority has been granted by the Army Council.

ARMY CLOTHING AND INFECTIOUS DISEASE.—The Home Office has called the special attention of local authorities to the fact that they possess full powers under the Factory Act to prevent outwork being done in any house where there is infectious disease. In view of the great quantity of home work that has necessarily to be done in connexion with the manufacture of army clothing, local authorities are called on strictly to enforce the provisions of the Act.

SURGICAL APPLIANCES FOR SOLDIERS.—The War Office has notified that disabled soldiers duly certified as needing artificial limbs or surgical appliances can receive them at the public expense by making application in writing to the Commissioners of the Royal Hospital, Chelsea, London, S.W.

DENTAL SURGEONS FOR THE ROYAL NAVAL VOLUNTEER RESERVE.—The Lords Commissioners of the Admiralty have sanctioned the addition to the establishment of the Royal Naval Volunteer Reserve of two temporary officers entitled dental surgeons. They will hold relative rank with surgeons of the Royal Naval Volunteer Reserve, and the pay will be £1 a day with compensations, pensions, and allowances on the same scale and under the same conditions as for surgeons of the Royal Naval Volunteer Reserve.

A MOTOR AMBULANCE FOR THE FRENCH RED CROSS.—A motor ambulance has been presented to the French Red Cross by the members of the Athenæum Club, who have already given one to the British Red Cross.

A POPULAR lecture, under the joint auspices of the Chadwick Trust and the League of Mercy, on the War and the Wounded, 1870-71, 1914-15 (illustrated by lantern slides), will be given by Mr. Adolphe Smith, Sanitary Commissioner to THE LANCET, who served in the French Ambulances during the Siege of Paris, in the lecture hall, Royal Society of Arts, John-street, Adelphi, W.C., to-day, Friday, March 12th, at 5.15 P.M. The chair will be taken by Sir William J. Collins, K.C.V.O., M.D. Admission free.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At a meeting of the Court of Assistants held at Apothecaries' Hall, Blackfriars, London, E.C., on March 9th, the honorary freedom of the society was conferred upon Sir Ronald Ross, K.C.B., F.R.S., in recognition of the very valuable services rendered by him to medical science, especially in connexion with the prevention of tropical disease. At the same meeting grants were made to various charitable funds in connexion with the war.

QUEEN'S HOSPITAL, BIRMINGHAM.—The seventy-fourth annual report of the Queen's Hospital, Birmingham, which was submitted to the board of governors at the hospital on March 10th, shows that during the year 1914 the number of in-patients treated was 2966 and the number of out-patients 28,430. The income was £11,827 and the expenditure £18,387, leaving a deficit of £6560. As in the case of other hospitals, the staff has been depleted owing to the war, but much excellent work has been done in administering to the needs of English and Belgian wounded soldiers.

THE National Health Insurance Commission (England) have issued a circular (AS. 161) dealing with the certificates of medical men attending panel patients in a private capacity, and giving the official reason why the forms Med. 40 have not been supplied to practitioners for use in these cases.

THE Editor of the *Journal of the Canadian Medical Association*, Dr. Andrew Macphail, announcing a change of address, asks that in future books, periodicals, and communications intended for the journal should be addressed to him at 836, University-street, Montreal.

Mr. R. Thomas Jones, L.R.F.P.S. Glasg., L.S.A. Lond., of Harlech, has been appointed High Sheriff for the county of Merioneth for 1915-16.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Naval Medical Compassionate Fund Bill.

THE Naval Medical Compassionate Fund Bill has been read a third time in the House of Lords. It has also passed through all its stages in the House of Commons, and it is therefore ready to receive the Royal Assent. In the House of Lords there was some disposition to inquire whether the fund with which the Bill deals was not being diverted from the purpose for which it had been originally subscribed. The representative of the Government, however, stated that the distribution of the fund would be settled by an order to be laid on the table of the House. The Bill was then permitted to pass through its remaining stages.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 3RD.

Pay of Territorial Medical Officers.

Mr. JOYNSON-HICKS asked the Financial Secretary to the War Office what were the rates of pay for captains in the Territorial Royal Army Medical Corps who went to the front as compared with pay given to civilian doctors for the same work.—Mr. H. BAKER wrote in reply: The present emoluments compare as under:—Emoluments of captains of the Royal Army Medical Corps, Territorial Force, when serving at the front: Pay (per day), 15s. 6d.; field allowance, 3s. 6d.; lodging, 3s.; fuel and light, 1s. 3d.—total 23s. 3d. Emoluments of civil surgeons commissioned as temporary lieutenants, Royal Army Medical Corps, under the same conditions: Pay (per day), 24s.

Sickness Benefit in Ireland.

Mr. GINNELL asked the Chancellor of the Duchy, as representing the National Insurance Commissioners, a series of questions in regard to the administration of sickness benefit in Ireland.—Mr. MONTAGU replied that he would be glad to make inquiry into any case that was brought to his notice where undue delay or difficulty had been experienced in obtaining a certificate to support a claim for sickness benefit. As regards these claims, the medical men who were giving certificates under the National Insurance Acts had arranged convenient places in their districts at which insured persons might attend for examination, and in any case where an insured person was prevented by distance or by his physical condition from leaving his own home he must be visited by the doctor in his own home. It was the duty of Approved Societies to scrutinise all claims for sickness benefit, and where the necessary conditions were fulfilled to their satisfaction benefit was payable from the fourth day of incapacity for work. As regards the basis on which grants had been made to facilitate the provision of medical certificates in Ireland, the Chancellor of the Exchequer stated on August 14th, 1913, that he was satisfied that a grant of £50,000 was insufficient to cover the cost of satisfactory arrangements for this purpose, and undertook to ask Parliament to increase the grant up to a maximum limit of 2s. 6d. per insured person per annum. This latter sum was equivalent to a sum of £97,100 per annum, and the estimates provided that payments out of the account under this head should be subject to conditions determined by a scheme made by the Irish Commissioners, with the approval of the Treasury. Pending the approval of such a scheme expenditure might be incurred for the purpose of certification in Ireland to an annual amount not exceeding £50,000 voted for this purpose. The present annual expenditure was about £44,000, the remuneration paid being inclusive of travelling expenses.

Mr. GINNELL asked the right honourable gentleman what independent medical approval, if any, the Irish Insurance Commissioners had for allowing insured poor persons seriously ill to be improperly disturbed by a certifier who, not being the medical attendant, was unacquainted with the cases, and for the Commissioners' more recent attempt to have laymen appointed to visit cases which they had no qualification for judging and from some of which they might convey infection; and whether, before allowing those two practices to proceed further, he would have them considered by the highest medical and surgical authorities in Ireland.—Mr. MONTAGU wrote in reply: I am informed that doctors who visit insured persons desirous of obtaining medical certificates are instructed to exercise every care in visiting persons who are seriously ill and are not permitted to interfere with the treatment prescribed by the doctor in attendance. If I correctly understand the second part of the question to refer to the appointment of sick visitors by Approved Societies, I may say that a system under which such visitors are appointed is of much value to Approved Societies in exercising a proper supervision over claims for sickness benefit. As regards the third part of the question, the Irish Insurance Commissioners are, as I myself am, of course, happy at any time to receive suggestions for the improvement of the existing system of certification. The right honourable gentleman added, in reply to another question, that any work in connexion with certification was only undertaken by Poor-law medical officers on the distinct understanding that it would not interfere with the proper performance of their other duties.

THURSDAY, MARCH 4TH.

Antityphoid Inoculation.

Mr. TENNANT, Under Secretary for War, informed Mr. CHANCELLOR that there had not been any change in the instructions with reference to antityphoid inoculation in the army.

The Sanitary Condition of Soldiers' Billets.

Mr. HOGGE asked the President of the Local Government Board whether he called for reports from local sanitary authorities as to the conditions of soldiers' billets; and

whether he would make any special inspection of those districts where large numbers of men were billeted.—Mr. HERBERT SAMUEL replied: Last autumn the Local Government Board, after consultation with the War Office, issued circular letters to local authorities indicating the action which should be taken by the authorities and their officers to give assistance in connexion with the sanitary condition of military quarters and other matters affecting the health of troops, including the systematic inspection of billets. I have received a number of reports from medical officers of health on camps and billets in their districts. Since the outbreak of the war my medical inspectors have visited camps and billets in all parts of the country and have made inquiries with respect to their sanitary condition and the action of local authorities and their officers in the matter. Up to the end of January about 550 such visits had been made. In addition to local representations by the inspectors action has been taken on their reports by the Board in cases where this was necessary by means of communications with the War Office and the local authorities.

Mr. HOGGE: Has my right honourable friend any report of the cases in which soldiers themselves have got rid of mattresses by burning them on account of their insanitary condition?—Mr. HERBERT SAMUEL: I have not had brought to my notice any such report, but if the honourable Member can give me any particular case I shall be glad to investigate it.

Mr. ALDEN: Has the right honourable gentleman received any complaints from the local authorities?—Mr. HERBERT SAMUEL: There have been representations which have been handed on to the War Office, but there has been no case of difficulty in providing a remedy in each case so far as I am aware.

Mr. JONATHAN SAMUEL: Is there any objection on the part of the military authorities to visits by the medical officers of health?—Mr. HERBERT SAMUEL: No. So far as I am aware the military authorities are most anxious to have the assistance both of the officers of the Local Government Board and the local officers of health to secure the best sanitation they can.

Sick and Wounded Soldiers in Hospitals.

Mr. HARRY LAWSON asked the Financial Secretary to the War Office what was the basis upon which contributions were made to the voluntary hospitals which, with the approval of the War Office, were admitting sick and wounded soldiers; whether such basis of contributions was uniform throughout the United Kingdom or whether a varying scale had been adopted; and, if so, upon what principle such variations were made.—Mr. H. BAKER answered: I am glad to say that the use of these voluntary hospitals has not been offered on a commercial basis, and the assistance given from public funds has taken the form of a grant-in-aid on the basis of a daily rate per occupied bed. The rate is normally 2s., but in some cases a somewhat larger grant may be given by the general officer commanding.

Mr. LAWSON: Will a difference be made between general hospitals in the metropolitan area and other hospitals?—Mr. BAKER: I cannot answer that question without notice.

Promotion in the Royal Army Medical Corps.

Sir C. KINLOCH-COOKE asked the Under Secretary for War whether there had been any cases of junior officers of the Royal Army Medical Corps promoted for services during the war, and, if not, why this corps should have been exceptionally treated in this respect.—Mr. TENNANT said in reply: Four majors have been promoted to be brevet-lieutenant-colonels. Decorations have also been conferred on 13 majors, 12 captains, and 9 lieutenants.

MONDAY, MARCH 8TH.

Sight Tests in the Mercantile Marine.

Mr. LYNCH asked the President of the Board of Trade whether his attention had been lately drawn to the inefficiency of the sight tests used by the Board; whether these tests had been adversely commented on by a great number of authoritative members of the medical profession; whether he would take steps to secure the best type of lantern available; whether it was found that the wool test allowed over 50 per cent. of dangerously colour-blind candidates to pass and produced the rejection of over 50 per cent. of normal-sighted candidates; and whether he would abolish this test altogether.—Mr. RUNCIMAN said in reply: I have reason to believe that the sight tests employed by the Board of Trade are efficient for their purpose, and that the criticisms made on the lantern are unfounded. The lantern test was submitted about a year ago to a rigorous practical test at Shoeburyness in the presence of representatives of shipowners, shipmasters, and others who had raised objection to its use, and as a result these objections were formally withdrawn. The figures as to the operation of the wool test are not entirely accurate, but the wool test has now become quite a subordinate part of the examination and no candidate is finally passed or rejected on this test alone.

The question whether the wool test can be dispensed with as superfluous is receiving consideration, but in present circumstances I should prefer to have somewhat longer experience of the new system before finally deciding the matter.

Mr. LYNCH: Will the right honourable gentleman undertake to defend the wool test scientifically?—Mr. RUNCIMAN: I have already said that I should prefer to have some longer experience of the new system before expressing any opinion upon it.

School Drill and Medical Opinion.

Sir J. D. REES asked the President of the Board of Education whether medical opinion other than that of the medical branch of the Board of Education had been sought in order to confirm the opinion of such medical branch to the effect that for children up to 14 or 15 it was most desirable that military drill should not be introduced into elementary schools.—Mr. J. A. PEASE replied: The answer is in the negative, as no occasion has arisen for such a consultation. In 1902 the Board issued a "Model Syllabus of Physical Exercises" which was largely based on military drill. In 1904 an Inter-departmental Committee, which included two medical men, unanimously reported that they did not consider the model syllabus suitable for use in schools, and recommended the adoption of a scheme based upon well-defined physiological and educational principles. When considering the revision of the syllabus in 1909 the Board had the advantage of informal consultation with a number of medical authorities.

Mr. WHITEHOUSE: Will the right honourable gentleman say whether the statement in this question as to the opinion of the medical branch of the Board of Education is correctly given?—Mr. PEASE: I cannot say as to the precise words without reference to the medical report, but I know that the opinion of my medical adviser is that the physical system at present in use in the elementary schools in this country is much the best kind of exercise and drill which those children can undergo.

TUESDAY, MARCH 9TH.

Private Houses as Military Hospitals.

Sir WILLIAM BULL asked the President of the Local Government Board whether he could see his way to arrange that private houses which were lent for the purpose of naval or military hospitals were free of rates while so used.—Mr. HERBERT LEWIS (on behalf of Mr. HERBERT SAMUEL) replied: The Local Government Board have no power to take any action of the kind suggested in the question. They have, however, stated in answer to inquiries that if a local authority in such a case should see fit to exempt such premises from rating the Board themselves would not, in the present circumstances, wish to take exception to such a course.

The Health Conditions of Osborne.

Lord CHARLES BERESFORD asked the Secretary to the Admiralty whether, with regard to the unhealthy condition of Osborne College, in which there were now 136 cases of illness, and having regard to the constant state of ill-health among the cadets and the fact that the college was built over old stable drains and soil sodden with tetanus germs and the prevalence of the complaint called pink eye, the Admiralty would appoint a commission of medical men to inquire into and report on the case.—Mr. MACNAMARA replied: There has been no case of tetanus at Osborne and no epidemic, but only isolated cases of the form of conjunctivitis alluded to by the noble lord as "pink eye" during the last two years. I may say that investigations were held in 1905 by the members of the Medical Consultative Board, together with Mr. Fisher, oculist, and independently by Dr. Louis Parkes, the sanitary expert, and again in 1910 by Dr. Louis Parkes and Dr. A. E. Russell. Practically all the alterations and improvements recommended in the reports of these commissions have been carried out. Further, from time to time other medical men have visited and reported on Osborne. It is not considered necessary to adopt now the suggestion contained in the last sentence of the noble lord's question.

Sequence of Illnesses in Metropolitan Asylums Board Hospitals.

Mr. TOUCHE asked the President of the Local Government Board whether he was aware that A. B., aged 3 years, who was removed to the Metropolitan Asylums Board Fever Hospital, Homerton-grove, on or about Oct. 9th last, suffering from scarlet fever, was subsequently reported to be doing well, then to have contracted chicken-pox, then to be quite well again and soon to be discharged, and then to be suffering from diphtheria; would he say whether a sequence of illnesses was common in the experience of the hospitals of the Metropolitan Asylums; and would he cause inquiries to be made as to the possibility of adopting improved methods of treatment, especially as regards the exposure of convalescents to risk of infection.—Mr. HERBERT SAMUEL furnished the following written reply: I am informed by the managers of the Metropolitan Asylums Board that A. B., age 2½, was admitted to the Eastern Hospital, Homerton, on Oct. 10th, certified to be suffering

from scarlet fever. The attack was mild and she was placed in a ward of 20 beds reserved for scarlet fever patients. On Dec. 11th she developed chicken-pox, which there is no doubt at all was introduced into the ward by a patient from outside who was admitted suffering from scarlet fever and also incubating chicken-pox, which shortly afterwards developed. A. B. was promptly isolated, along with two other patients who were suffering from scarlet fever and chicken-pox (all three being removed from the same ward). On Feb. 22nd A. B. showed signs of diphtheria and from that date she has been in a separation ward by herself. I am also informed that post-scarlatinal diphtheria is unfortunately not uncommon, in fact there are some grounds for stating that an attack of scarlet fever predisposes to an attack of diphtheria. Such cases of diphtheria occurring in a scarlet fever ward may be due to an unrecognised case of diphtheria or to the presence in the ward of a carrier case. Such cases are quite frequent among school children, and it is possible that A. B. was herself a carrier case and that the diphtheria bacilli in her throat became active after her prolonged illness. No other case of diphtheria has occurred in either of the wards in which she was treated. In reply to the second paragraph of the honourable Member's question, I am informed that it is quite uncommon to have such a sequence of illnesses in the Metropolitan Asylums Board's hospitals, and even secondary diseases are relatively uncommon, especially when one considers the frequency with which children are exposed daily to infection in schools and crowds. The ratio of the following complications of scarlet fever cases in 1913 (the latest return available) and 1903 respectively was per 100 cases:—

	1903.	1913.
Diphtheria	2.32	1.36
Chicken-pox	2.36	1.48

In reply to the third paragraph, I may say that the question of improved methods of treatment is at no time lost sight of by the managers and their advisers, and the figures given above show that the structural and other provision which has been made to reduce the risk of cross-infection to which all fever hospitals are liable has not been unsuccessful.

Uncertified Mental Patients.

Mr. ALDEN asked the President of the Local Government Board whether he was prepared, in accordance with the tenor of the memorial signed by 330 Members of Parliament and 236 doctors which was presented to him last July, to grant permissive powers to the London County Council and other county councils to form a committee to manage and maintain a hospital which uncertified mental patients might enter voluntarily to receive the early treatment most conducive to their cure.—Mr. HERBERT SAMUEL wrote in reply: I would refer my honourable friend to my reply to a similar question on March 1st. I have no authority to confer on county councils the powers suggested in the question, but my honourable friend will see on reference to the London County Council (General Powers) Bill that the County Council are seeking powers to receive in a hospital cases of the kind mentioned.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ANGUS, WILLIAM, M.D. Aberd., D.P.H. Cantab., has been appointed Acting Medical Officer of Health for Leeds.
BLUMFELD, JOSEPH, M.B., B.C. Cantab., has been appointed an Honorary Anaesthetist to King Edward VII.'s Hospital for Officers.
CARRINGTON, G. H., M.R.C.S. Eng., D.P.H., has been appointed Temporary Assistant School Medical Officer to the Durham Education Committee.
CLAPHAM, E. W., M.R.C.S., L.R.C.P. Lond., has been appointed an Honorary Anaesthetist to King Edward VII.'s Hospital for Officers.
COLLINGS, D. W., M.B. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Southwold District of the county of Suffolk.
HOBHOUSE, E. W. N., M.B., B.Ch. Oxon., has been appointed Resident Medical Officer at the City of London Hospital for Diseases of the Chest, Victoria Park, N.E.
HYNES, LOUIS A., L.A.H. Dub., has been appointed Temporary Assistant School Medical Officer for Torquay.
LOW, V. WARREN, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed External Examiner in Surgery at the University of London.
MAGEE, J. R., L.R.C.P. & S. Irel., has been appointed Port Medical Officer at Londonderry.
ROSS, R. H., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Clogher District of the county of Tyrone.
SMITH, R. TRAVERS, M.D. Dub., F.R.C.P., has been appointed Professor of Materia Medica, Therapeutics, and Pharmacy at the Royal College of Surgeons in Ireland.
SPENCE, R. J., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Stewartstown District of the county of Tyrone.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

- AYLESBURY, ROYAL BUCKINGHAMSHIRE HOSPITAL.—Locum Tenens House Surgeon.
- ASHTON-UNDER-LYNE DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with residence, board, &c.
- BENENDEN, KENT, NATIONAL SANATORIUM.—Assistant Medical Officer. Salary £120 per annum, with board, residence, and laundry.
- BETHNAL GREEN INFIRMARY, Cambridge-road, N.E.—Assistant Medical Officer. Salary at rate of £280 per annum, with apartments, board, and washing.
- BIRKENHEAD BOROUGH HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board and laundry. Also Junior House Surgeon. Salary £100 per annum, with board and laundry.
- BIRMINGHAM, CITY MENTAL HOSPITAL, Winslow Green.—Assistant Medical Officer. Salary £250 per annum, with apartments, board, laundry, &c.
- BIRMINGHAM GENERAL HOSPITAL.—Honorary Surgeon. Also an additional Assistant Surgeon. Salary at rate of £50 per annum.
- BIRMINGHAM, QUEEN'S HOSPITAL.—Two House Physicians. Salary at rate of £80 per annum, with board, apartments, washing, and attendance.
- BOLTON INFIRMARY AND DISPENSARY.—Senior House Surgeon and Second House Surgeon. Salary £230 and £200 per annum respectively, with apartments, board, and attendance.
- BOXTLE BOROUGH HOSPITAL.—Senior and Junior House Surgeons. Salary £150 and £130 per annum respectively, with residence, board, and laundry.
- BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL.—House Surgeon for six months. Salary £100 per annum, with board, lodging, washing, &c.
- BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.
- BRISTOL EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.
- BRISTOL GENERAL HOSPITAL.—Resident Obstetric Officer for six months. Salary at rate of £120 per annum, with board, residence, &c.
- BRISTOL ROYAL INFIRMARY.—Three House Surgeons. Two House Physicians, and One Obstetric and Ophthalmic House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.
- BROOKWOOD, SURREY COUNTY ASYLUM.—Junior Assistant Medical Officer. Salary £250 per annum, with board, lodging, and laundry.
- BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £135 per annum, with residence, board, and washing.
- BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing.
- CAMBERWELL, CONSTANCE-ROAD INSTITUTION, East Dulwich, S.E.—Temporary Resident Medical Officer. Salary at rate of £350 per annum, with apartments, board, washing, &c.
- CANTERBURY, KENT COUNTY ASYLUM, Chartham.—Third Junior Assistant Medical Officer. Salary £250 per annum, with quarters, board, washing, &c.
- CANTERBURY MENTAL HOSPITAL.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, washing, and attendance.
- CARLISLE, CUMBERLAND INFIRMARY.—House Physician for six months. Salary as arranged.
- CARLISLE, CUMBERLAND AND WESTMORLAND ASYLUM, Garlands.—Junior Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, and washing.
- CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.—Resident House Surgeon. Salary £50 per annum, with board and residence.
- CHELTENHAM GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.
- CHESTERFIELD, BOROUGH OF.—Medical Officer of Health. Salary £500 per annum.
- COLCHESTER, ROYAL EASTERN COUNTIES' INSTITUTION FOR IMBECILES AND THE FEEBLE-MINDED.—Female Medical Officer. Salary at rate of £200 per annum, with board, apartments, attendance, and washing.
- DERBY, DERBYSHIRE HOSPITAL FOR SICK CHILDREN.—Female Resident Medical Officer for six months. Salary £200 per annum.
- DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board and laundry.
- DEWSBURY AND DISTRICT GENERAL INFIRMARY.—House Surgeon. Salary £170 per annum, with board, residence, and laundry.
- DUDDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Also Assistant House Surgeon for six months. Salary £150 and £120 per annum respectively, with board, residence, attendance, and washing.
- DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Resident House Surgeon. Salary £120 per annum.
- DUNDEE ROYAL INFIRMARY.—Resident Medical Officers. Salary £100 per annum.
- ECCLES AND PATRICROFT HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board, residence, and laundry.
- GLASGOW, CORPORATION OF THE CITY OF.—Vacancies among Junior Resident Medical Staff of City of Glasgow Fever Hospitals. Salary at rate of £160 per annum. Also Assistant Bacteriologist (two vacancies). Salary £250 per annum.
- GRANGE-OVER-SANDS, WESTMORLAND CONSUMPTION SANATORIUM AND HOME, Meathop.—First and Second Assistants to Medical Superintendent. Salary £250 and £200 per annum respectively, with apartments, board, and laundry in each case.
- GRIMSBY AND DISTRICT HOSPITAL.—House Surgeon.
- HALIFAX ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.
- HEREFORD COUNTY AND CITY ASYLUM.—Assistant Medical Officer, unmarried. Salary £250 per annum, and all found except stimulants.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas. Also Physician.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £30, with board, residence, &c.
- HOSPITAL FOR WOMEN, Soho-square, W.—Resident Medical Officer for six months. Salary at rate of £30 per annum.
- HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—Resident House Surgeon and Resident Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry. Also Resident House Surgeon. Salary £100 per annum, with board and laundry.
- INVERNESS, NORTHERN INFIRMARY.—House Surgeon. Salary £150 per annum, with board, &c.
- ITALIAN HOSPITAL, Queen-square, W.C.—House Surgeon for six months. Salary £30 per annum, with board and residence.
- LEEDS, GENERAL INFIRMARY.—Resident Medical Officer for six months at Ida and Robert Arthington Hospitals. Salary £60 per annum, with board, residence, and laundry.
- LEICESTER ROYAL INFIRMARY.—Ophthalmic House Surgeon, &c. Salary at rate of £100 per annum, with bonus, board, apartments, and washing.
- LIVERPOOL COUNTY ASYLUM, Rainhill.—Temporary Assistant Medical Officer. Salary £6 6s. per week, with apartments, board, attendance, and washing.
- LIVERPOOL ROYAL INFIRMARY.—Two House Physicians, Three House Surgeons, and One House Surgeon to Gynaecological Department, all for six months. Salary at rate of £60 each per annum.
- LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Two House Surgeons and One House Physician, each for six months. Salary at rate of £60 per annum, with board and residence.
- MACCLESFIELD, CHESHIRE COUNTY ASYLUM, Parkside.—Junior Assistant Medical Officer. Salary £250 per annum, with apartments, board, laundry, &c.
- MANCHESTER, ANCOATS HOSPITAL, Mill-street.—House Physician. Salary £80 per annum, with board and residence.
- MANCHESTER CHILDREN'S HOSPITAL, Gartside-street.—Assistant Medical Officer for Out-patient Department, for six months. Salary £100 per annum.
- MANCHESTER, COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.
- MANCHESTER, EAST LANCASHIRE TERRITORIAL FORCE.—Officers in East Lancashire (Second Line) Field Ambulance.
- MANCHESTER, MONSIEUR FEVER HOSPITAL.—Second and Third Medical Assistants. Salary £175 and £150 per annum respectively, with board, lodgings, and washing.
- MERTHYR TYDFIL COUNTY BOROUGH.—Assistant School Medical Officer. Salary £300 per annum.
- MIDDLESBROUGH, NORTH ORMESBY HOSPITAL.—House Surgeon. Salary £150 per annum, with board, washing, and attendance.
- MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Senior House Surgeon for six months. Salary £100 per annum, with board, residence, and laundry.
- NEWPORT (MON.), ROYAL GWENT HOSPITAL.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.
- NORTH RIDING OF YORKSHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary at rate of £300 per annum.
- NORWICH, NORFOLK AND NORWICH HOSPITAL.—House Surgeon. Salary £150 per annum, with board, lodging, and washing.
- NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician for six months. Salary at rate of £100 per annum, with board, residence, and laundry.
- PAISLEY INFECTIOUS DISEASES HOSPITAL.—Resident Medical Officer. Salary £200 per annum, with board, washing, and attendance.
- QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary £100 per annum, with board, residence, and washing.
- ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Male and Female House Physicians and House Surgeons for six months. Board, lodging, and washing provided. Also Acting Assistant Physician to have Care of Out-patients. Also Female Senior Obstetric Assistant. Salary £75 per annum, with board, lodging, and washing. Also Female Junior Obstetric Assistant. Board, lodging, and washing provided.
- ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board and residence. Also Dental Surgeon.
- ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W.—Resident House Surgeon. Salary £100, all found.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William street, West Strand, W.C.—Assistant House Surgeon for six months. Salary at rate of £50 per annum.
- ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, M.—Junior Resident Medical Officer. Salary at rate of £90 per annum, with board, residence, and laundry.
- SALFORD ROYAL HOSPITAL.—House Surgeon, Junior House Surgeon, and Casualty House Surgeon. All for six months. Salary at rate of £100 per annum each, with bonus, board, and residence.
- SALFORD UNION INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £300 per annum, with apartments, attendance, and rations.
- SALISBURY GENERAL INFIRMARY.—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum respectively, with apartments, board, lodging, and washing.
- SECOND EAST ANGLIAN FIELD AMBULANCE.—Medical Officer. Pay and allowances as in Regular Army.
- SHEFFIELD CITY HOSPITALS (INFECTIOUS DISEASES AND TUBERCULOSIS).—Second Assistant Medical Officer. Salary £225 per annum, with board, apartments, attendance, and washing.
- SHEFFIELD ROYAL HOSPITAL.—Female Assistant House Surgeon and Female Assistant House Physician. Salary £85 and £80 per annum respectively, with board, residence, and washing.
- SHEFFIELD ROYAL INFIRMARY.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.
- SHEFFIELD UNIVERSITY.—Joseph Hunter Chair of Pathology.

Notes, Short Comments, and Answers to Correspondents.

SIR THOMAS LONGMORE AND THE CARE OF OUR WOUNDED.

IN THE LANCET of Oct. 3rd, 1914, we published a leading article on the Care of Our Wounded, in which we mentioned that the scheme for the care of our wounded was laid down many years ago by Sir Thomas Longmore, and that it lent itself to various developments. In his address before the Section of Military Surgery and Medicine of the International Congress of Medicine held in London in 1881¹ Sir Thomas Longmore finished by saying: "The sketch I have laid before you of the existing arrangements for ensuring help and skilled attention to the wounded in case of this country unhappily becoming involved in war has been unavoidably a superficial and imperfect one, and I must apologise for its incompleteness." Those who are studying the improvements of ambulance transport in the various competitions that have been recently announced might be interested to look at Sir Thomas Longmore's interesting book on ambulances published in 1869, with its voluminous information and illustrations of inventive enterprise.

THE METRIC SYSTEM.

To the Editor of THE LANCET.

SIR.—With reference to your comments of March 6th (p. 506) on a possible danger in connexion with the metric system in prescribing may I suggest that during the period of transition it would hardly be fair to leave the onus of the transposition of formulæ to rest entirely on the dispenser. Since the metric system became official I have employed both formulæ, one on the left and the other on the right hand margin of the prescription. I think that practice might with mutual advantage be adopted in the immediate future.

I am, Sir, yours faithfully,
Harley-street, W., March 8th, 1915. W. BEZLY THORNE.

CENTIGRADE AND FAHRENHEIT.

To the Editor of THE LANCET.

SIR.—Your correspondents who wish to know an easy way of changing Centigrade into Fahrenheit would find the following method both simple and accurate. Double the number of C. degrees, deduct a tenth and add 32. Such a calculation can be made without the aid of pen and paper.

I am, Sir, yours faithfully,
AUG. HADLEY.
Craven-street, Strand, W.C., March 5th, 1915.

"SHELL FUMES AND PNEUMONIA."

IN a letter to the *Times* under the above heading Sir William Ramsay suggests that the acute pneumonia which, it is reported, often develops after a man has been exposed to the fumes of a bursting shell are due to nitric peroxide. As this gas is readily soluble in water it may be rendered harmless by passing it through a moist cloth. Such a precaution is adopted by the workers in bleaching-powder chambers to keep the chlorine from entering the lungs. To guard against a sudden exposure to gas a well wrung-out wet handkerchief or any bit of cloth is stuffed into the mouth and air breathed through it, the return air being discharged through the nose. Sir William Ramsay's suggestion should be generally known.

A NEW METHOD OF STERILISATION.

To the Editor of THE LANCET.

SIR.—In your issue for Jan. 23rd appears an annotation on an article in the *Gazzetta degli Ospedali* by Dr. Guido Cremonese, drawing attention to the value of iodobenzene as a disinfectant. May I be permitted to record my own three years' observations on the use of that antiseptic product?

Some three years ago I was operating upon a valuable pedigree Devon bull for a subparotideal actinomycotic growth, the capsule of which, distended with pus, was very attenuated; and in the process of dissection and removal the virulent pus escaped, contaminating the surgical wound, which in my experience nearly always leads to a recurrence unless active measures are adopted to counteract the infection. I had an ounce of tincture of iodine with me, but the cavity having a capacity of 300-500 c.c. this dressing for packing would not go far. I obtained about 10 oz. of petrol from my car and mixed it with the tincture of iodine, and I confess to no small degree of disappointment when I recognised the two did not mix well.

¹ THE LANCET, August 6th, 1881, p. 240 et seq.

Births, Marriages, and Deaths.

BIRTHS.

BROAD.—On March 4th, at Rodney-street, Liverpool, the wife of W. H. Broad, M.D., B.S., of a son.
SPARKS.—On Feb. 28th, at Whitley Bay, the wife of Dr. J. P. Sparks, of a son.
TRAILL-THOMSON.—On Feb. 26th, at The Parade, Leamington, the wife of Dr. W. Traill-Thomson, of a daughter.

MARRIAGES.

BOYS STONES—GIBBS.—On Feb. 23rd, at St. Saviour's Church, Torquay, William Boys Stones, B.A., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., to Florence Maud, second daughter of J. T. Gibbs, of Torquay.
GOODWIN—RUDHALL.—On Feb. 18th, at St. Peter's, Belsize-square, Lieutenant Aubrey Goodwin, R.A.M.C., to Elsa, daughter of the late John P. Rudhall and Mrs. Rudhall, of Belsize Park-gardens.

DEATHS.

ELLIOTT.—On Feb. 26th, at Sussex-street, Winchester, Gilbert Elliott, M.M.C.S., L.R.C.P., D.P.H., D.T.M., aged 44 years.
HARNETT.—On March 1st, at Belvedere House, Barnet, suddenly, William John Harnett, F.R.C.P. Edin., late Surgeon-Major, 22nd Middlesex R.V., aged 70 years.
MCALLUM.—On Feb. 26th, Donald C. A. McAllum, M.B., C.M.
RICHARDS.—On March 5th, killed in action, at Neuve Eglise, Francis Graham Richards, Major, Royal Army Medical Corps.
SIEVEKING.—On March 10th, at Devonshire-terrace, Hyde-park, W., Jane, widow of Sir Edward Sieveking, M.D. Edin., F.R.C.P. Lond., in her 90th year.
STUART.—On March 9th, the result of a motor accident, Francis Arthur Knox Stuart, B.A. Camb., L.S.A. Lond., Senior Assistant Medical Officer, Graylingwell Hospital, Chichester, son of the late Major Burleigh Stuart, of Omagh, and of Mrs. Stuart, Ranelly, Crowborough, aged 39 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

However, I had the cavity well flushed out with a strong solution of citrate of soda and then firmly plugged with tampons soaked in the iodine and petrol solution. While applying the dressing I was greatly struck with the amount of powerful vapour emanating from the dressing, which had a most irritating effect upon one's eyes. The operation wound healed well, and I saw the patient quite recently and there was no sign of a recurrence. Since then I have used the iodine and petrol dressing as a matter of routine in my practice, amounting in all to well over 300 patients, in such cases as fistulous wounds and deep-seated punctures, surgical cavities which have been contaminated, also for the sterilisation of skin prior to operations in neurectomies, tenotomies, ovariectomies, hysterectomies, and the removal of neoplasms.

The great therapeutical value of the dressing appears to be summed up in its powers of penetration, and unlike so many antiseptics it does not retard the phagocytic action or lower the bacteriotropic powers of the fluids flushing the wounds. For this reason the dressing has been found most useful in wounds infected with such virulent bacteria as bacillus oedematis maligni, B. chauvæi, B. tetani if applied early and thoroughly enough. Finally, by reason of its cheapness it should commend itself to veterinary practice, at least when in some cases several ounces require to be used at each dressing.

I am Sir, yours faithfully,

W. M. SCOTT, F.R.C.V.S.,

Consulting Veterinary Surgeon for the
County of Somerset.

March 4th, 1915.

THE "CRAIGLEITH HOSPITAL CHRONICLE."

THE third monthly issue (February) of the *Craigleith Hospital Chronicle* contains a portrait of Surgeon-General G. D. Bourke, C.B., the Deputy Director of Medical Services in Scotland. One of the results of the war has been the very natural desire on the part of those not in the Services or who have only recently joined to know the meaning of the thousand and one military terms that constantly occur in the newspapers and elsewhere, and the serial articles in this *Chronicle* supply this kind of information. The Notes on the Army this month deal with the Artillery. The magazine may be obtained, price 6d., from the Second Scottish General Hospital, Craigleith, Edinburgh.

WHAT IS NORMAL TEMPERATURE?

To the Editor of THE LANCET.

SIR,—In THE LANCET of March 6th (p. 530) "Grimpeur" speaks of "the daily range of temperature in health—namely, from 97° to 98.4°." Surely if that were the case the normal line on our charts and thermometers should stand at 97.7°. I have always supposed the daily range to extend on either side of 98.4°—say from 97.8° to 99°—and so should regard 99° as a less abnormal figure than 97°.

I am, Sir, yours faithfully,

H. ALSTON, M.D.

West Norfolk and Lynn Hospital, King's Lynn,
March 8th, 1915.

"WHAT EVERY SOLDIER OUGHT TO KNOW."

THIS little work consists mainly of extracts from official text-books and training manuals, and is an attempt to provide the private soldier with as much rudimentary knowledge of his profession as may conveniently be conveyed in print and in the smallest possible compass. Care has been taken to convey the spirit as well as the letter of the authorised books of instruction, and the few sentences about preservation of health are clear and to the point. It can be obtained from Humphrey Milford, Oxford University Press, Amen Corner, London, E.C., price 2d.

TUBERCULOSIS SANATORIUMS.

A USEFUL list of sanatoriums and other residential institutions approved by the Local Government Board under the National Insurance Act for the treatment of persons resident in England (excluding Monmouthshire) who suffer from tuberculosis has been issued by the Board and revised up to Feb. 20th. It may be obtained, price 1d., either directly or through any bookseller, from Messrs. Wyman and Sons, Limited, 29, Bream's-buildings, Fetter-lane, London, E.C.; H.M. Stationery Office (Scottish Branch), 23, North-street, Edinburgh; or E. Ponsonby, Limited, 116, Grafton-street, Dublin.

Specimen sheets of a "Sanatorium Case Register," designed by Mr. G. M. Mayberry, B.A., L.R.C.P., have also reached us. The size of each page is 11½ in. wide by 16½ in. deep. Two opposite pages form a record. The upper half of the left-hand page contains spaces for the necessary data concerning the patient up to and at the time of admission. The lower half shows duplicated clinical charts of the thorax, front and back, and of the larynx, in order to record for comparison the conditions

on admission and on discharge. Spaces are also left for results of treatment, remarks, urine and sputum, and tuberculin tests. The opposite page is left blank for notes, with a tabulated space for after-history six months, one year, and each year afterwards up to ten years. The books, which are supplied strongly bound with index to contain from 50 to 200 forms at prices from £1 5s. to £2, are published by Mr. H. K. Lewis, 136, Gower-street, London, W.C.

WANTED, A HOME.

To the Editor of THE LANCET.

SIR,—I should be much obliged if any of your correspondents would tell me of a home which would take a spinal case (fracture). No bedsores or urinary or rectal trouble. The patient is a collier and he is entitled to about £1 a week compensation. He is single, but his mother is in service—a caretaker in a London flat—and cannot therefore look after him.—I am, Sir, yours faithfully,

H. NEVILLE TAYLOR, M.A., M.D., F.R.C.S.,
Surgeon, Ebbw Vale Hospital.

Hillside, Ebbw Vale, Mon., March 8th, 1915.

S. J. B.—All the following small manuals on massage have been favourably reviewed in our columns on the dates indicated. "Lessons on Massage," by Margaret Palmer, Baillière, Tindall, and Cox, 1912, price 7s. 6d. net (April 6th, 1912); "Massage, its Principles and Technique," by Max Böhm, edited by Dr. Painter, W. B. Saunders Company, 1913, price 7s. 6d. (Nov. 8th, 1913); "Text-book of Massage and Swedish Gymnastics," by Dr. T. D. Luke, Scientific Press, 1913, price 2s. 6d. (June 14th, 1913); "Massage and Swedish Movements," by Kurre W. Östom, H. K. Lewis, 1912, price 3s. 6d. (Oct. 19th, 1912); "Massage," by Mabel M. Pireau, revised by Dr. Gurney Champion, Scientific Press, 1912, price 2s. 6d. net (Feb. 1st, 1913).

H. S. (Beckenham).—The report forwarded by our correspondent has already appeared in full in THE LANCET.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Bakerian Lecture: Prof. W. H. Bragg: X Rays and Crystals.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries—W. Langdon Brown, Philip Hamill, J. Gordon Sharp): at 4.30 P.M.

Professor A. R. Cushny, M.D., F.R.S.: (1) Notes on Diuresis; (2) Notes on the Antagonism of Drugs.

GENERAL MEETING OF FELLOWS: at 5 P.M.

Ballot for the Election of Candidates to the Fellowship.

WEDNESDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawford, Leonard G. Guthrie): at 5 P.M.

Professor A. R. Cushny, M.D., F.R.S.: William Withering.

Dr. J. A. Nixon: Thomas Baynton.

Dr. George C. Peachey: William Bronfield.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.

Exhibition of Cases (at 4.30 P.M.):

Dr. G. Pernet: (1) Erythema Induratum (Bazin); (2) Iodide Eruption and Syphilis.

Dr. W. K. Sibley: Case for Diagnosis.

Dr. S. E. Dore and Dr. Kinnier Wilson: Case for Diagnosis.

Dr. H. G. Adamson: Macular Atrophy.

Mr. H. C. Samuel (introduced): Linear Nævus.

FRIDAY.

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—S. Gilbert Scott, E. P. Cumberbatch): at 8.30 P.M.

Clinical Meeting.

Members wishing to show cases, instruments, lantern slides, or skiagrams for diagnosis, are requested to send a short account of these as soon as possible to the Senior Hon. Secretary, Mr. Gilbert Scott, 6, Bentinck-street, W., so that a list may be sent to the Members before the Meeting.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Cases sent for Consultation. Demonstration of Pathological Specimens. Clinical Cases will be shown by Dr. M. Dockrell, Dr. J. L. Bunch, Dr. W. K. Sibley, Dr. S. Gooding, and Dr. C. H. Mills. 5 P.M., Paper:—Dr. A. D. Bremner: The Importance of Detail in the Treatment of Diseases of the Skin.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Paper:—Dr. F. L. Pyman: Some Interesting Drugs of Tropical Origin.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY.—5 P.M., Milroy Lecture:—Dr. E. L. Collis: Industrial Pneumoconioses, with Special Reference to Dust-phthisis.
 THURSDAY.—5 P.M., Lumleian Lecture:—Dr. S. Martin: Non-ulcerative Infections of the Colon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

WEDNESDAY, AND FRIDAY.—5 P.M., Prof. R. Farrant: The Effect of Toxins on the Tissues.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 12 noon, Lecture: Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
 THURSDAY.—5.15 P.M., Clinical Lecture.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

THURSDAY.—3 P.M., Dr. A. Strahan: The Form and Structure of the London Basin. (Lecture I.)

FRIDAY.—9 P.M., Prof. G. H. Bryan: The Modern Piano Player—Scientific Aspects.

SATURDAY.—3 P.M., Prof. Sir J. J. Thomson, O.M.: Recent Researches on Atoms and Ions. (Lecture V.)

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Mr. H. Platt: Internal Derangements of the Knee-joint.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1914 were given in THE LANCET of Dec. 26th, 1914.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 are now ready. Bound in cloth, gilt lettered, price 16s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	...	...	£1 1 0	One Year	...	...	£1 5 0
Six Months	...	...	0 12 6	Six Months	...	...	0 14 0
Three Months	...	...	0 6 6	Three Months	...	...	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.
Special Terms for Position Pages.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.
Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.
Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.
The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County & Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.
THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agents for the Advertisement Department in France—SOCIÉTÉ EUROPÉENNE DE PUBLICITÉ, 10, Rue de la Victoire, Paris.

The Morison Lectures

ON

THE NEW PSYCHIATRY.

*Delivered before the Royal College of Physicians of Edinburgh
on March 8th, 10th, and 12th, 1915,*

By W. H. B. STODDART, M.D. LOND.,
F.R.C.P. LOND.,

LECTURER IN MENTAL DISEASE, ST. THOMAS'S HOSPITAL, ETC.

LECTURE I.

(Delivered on March 8th.)

FUNDAMENTAL PSYCHICAL MECHANISMS.

MR. PRESIDENT AND GENTLEMEN,—Before entering on my theme I wish to express my most sincere gratitude for the honour you have conferred on me by inviting me to deliver these lectures. To have my name associated with those of such eminent men as have preceded me in this chair is a dignity which I appreciate very highly, and it is also particularly gratifying to me to think that the founder, Sir Alexander Morison, was one of my predecessors as physician to Bethlem Royal Hospital in London. In those days the physician was non-resident; now he is resident, but it was a curious coincidence that I received your gracious invitation just as I had left my post of resident physician to that hospital to engage in consulting practice in Cavendish-square, within a few yards of Sir Alexander Morison's old house.

INTRODUCTORY REMARKS.

In respectful response to your kind invitation I have decided to expound the principles and practice of psycho-analysis rather than to weary you with crude trivialities of my own; for in the domain of mental disease this new psychiatry, which has not yet received sufficient recognition in this country, is one of the most important problems of the day. I have set myself the difficult task of compressing into the space of three hours the substance of a vast literature on an intrinsically difficult subject, concerning which a complete doctrine has not yet been elaborated, although an enormous amount of patient labour has been expended upon it during the last 20 years.

Psycho-analysis has, of course, met with captious criticism, the inevitable destiny of a new truth, and this has been especially severe in the case of our new psychiatry for four reasons: 1. The critics do not read psycho-analytic articles or they do so only superficially, so that they arrive at quite extraordinary misconceptions. 2. Not one of them has given the method a full and practical trial. 3. Basing their criticisms upon sentiment and prejudice, they assume an attitude of moral indignation or haughty contempt, seeking an answer to the question, "Are these principles to my liking?" instead of the question, "Are these principles true?" 4. The critics have been somewhat justified in that a number of medical men, especially in Germany, practise, in various sanatoriums and in private, what they conceive to be psycho-analysis, without having attempted to master the subject, with the result that they have done their patients more harm than good by filling their minds with all sorts of filthy ideas and making the most objectionable suggestions by way of therapeutic advice. I need hardly say that such charlatans, for they are neither more nor less, have through their ignorance

No. 4777.

brought discredit upon the new psychiatry which it does not deserve; for their methods, as I hope to show, are the very antithesis of those of psycho-analysis.

At the present time it would be asking too much of my audience to accept as a scientific truth doctrines which have had their birth in Austria and Germany, where truth appears to be monopolised by professors and divines for academic purposes only and scientific discoveries are prostituted for purposes of outrage and destruction of civilisation and all that civilisation means, were it not that I can give assurances that those doctrines have been tested and accepted by earnest workers and profound thinkers in Switzerland, America, and Great Britain. As a matter of fact, Freud himself has no German blood in him, but is a pure Jew, and, after all, science knows no nationality, and the account I present to you is an attempt at compromise between and combination of the opinions of many great men.

INSTINCT.

In order to gain a clear insight into the principles of abnormal psychology, let us by way of preliminary examine the human instincts.

Instinct is the blind prompting inherent in an animal to act without deliberation in a certain way. An instinctive action is practically perfect on the very first attempt, although there has been no previous education in its performance, and it is of such a nature as to produce certain ends without foresight of those ends. Instincts are perhaps most characteristic among the lower animals. As examples, sexual acts, migration, the first-year bird building her nest and sitting on her eggs, nutrition and care of the young, the lion stalking his prey, and the congregation of certain animals into shoals, flocks, and herds. In man one may instance the first attempt at speech by the human infant, the first attempts to walk, the avoidance of filth, making collections of all sorts of things, seeking the company of the opposite sex, nurture of the young, pulling down the blinds at night, and the congregation into towns and cities.

These are but a few examples, but even were the list complete it would be found possible to group all the instincts under two headings—viz., those subserving the function of preserving the individual and those subserving the function of perpetuating the race. They have also been classed into three categories, according as they are moved by the promptings of self-preservation, nutrition, or sex.

The Herd Instinct.

Now Dr. Wilfred Trotter, in two very able articles in the *Sociological Review* for 1908 and 1909, has drawn our attention to the existence and importance of a fourth instinct—gregariousness or, as he calls it, the herd instinct. Although this has long been recognised, it had never before been seriously contemplated and studied. When we come to think of it man is much more dependent upon communal life than appears at first sight. Left to himself he is not only extremely miserable, but his faculty of speech is useless to him and he stands little chance of survival among the other animals. Moreover, his conduct is very largely regulated by the customs of his tribe.

The advantage of gregariousness lies in the homogeneity of the herd, which enables large numbers to act in concert. In hunting and warfare, for example, the benefit of this is obvious, for the prey or enemy is more easily

vanquished by a large number of hunters than by a single unit. Such homogeneity is assured by an inherent impulse of each individual to behave in the same way as his fellows, and those who depart from the usual customs of the herd cease to benefit from the advantages of gregariousness, if they are not actually killed. The herd instinct, like other instincts, is maintained by natural selection.

So it happens that in company there is an unanalysable feeling of comfort; in solitude there is an unanalysable sense of restlessness and discomfort. This is just instinct. Similarly, if we depart from the customs of our particular "set" in matters of dress, amusement, religion, or politics, either we feel uncomfortable or we are regarded as eccentric and ostracised. Stage fright and shyness are the outcome of an instinctive desire to leave one's conspicuous position and to become once more one of the herd.

Dr. Bernard Hart recently drew my attention to the latter-day exemplification of the herd instinct in the fact that a man who worries about the ultimate result of the war ceases to do so when he enlists in Kitchener's army. He has the unconscious feeling of being within the fold.

Again, man is readily prepared to accept suggestions which are in accordance with the traditions of his particular herd; but he is disinclined to receive new truths which have been revealed by experience. People refused to look through Galileo's telescope, Darwin was considered a madman, the clinical thermometer was laughed at, people refuse to believe in vaccination or inoculation of any kind, new diseases are figments of the imagination of their discoverers, and psycho-analysis is immoral; because the new must always encounter the opposition of the herd tradition. But it must also be remembered that in such instances herd tradition has to encounter opposition from the new and may be gradually overcome until the experience becomes incorporated with the herd traditions.

In matters of opinion, however, such as politics, religion, finance, education, art, literature, and all sorts of public problems, the opinions of the people ranged on *both* sides are based on herd traditions, and no amount of argument will induce them to see the opposite point of view, or even to adopt the only rational position in such matters—viz., that of suspended judgment. On the contrary, they find more and more justification for the opinions they hold. In other words, belief comes first, reasons for the belief come second. This process is known as "rationalisation." It may, of course, be used in support of, or in opposition to, scientific truths; but even then "rationalisation" is dependent on the herd instinct for its existence.

How, then, are we to know whether any opinion we hold is rational or non-rational? If we find that we base the opinion on the feeling that any inquiry into the matter would be useless, barren, and superfluous, and that it is foolish, unpatriotic, wicked, or "bad form" to think otherwise, then it must be regarded as irrational, but if our opinion is based on experience then it is rational.

We have so far been discussing the influence of the herd instinct on intellectual processes, but we shall find that it also lies at the basis of our moral sentiments. Whenever a man does anything which he knows would meet with the disapprobation of his friends he experiences a feeling of uneasiness, similar to that caused by isolation, solitude or

separation from the tribe, a feeling of guilt, and when he does something which would be applauded by his fellows he has a sense of happiness and self-satisfaction. This is, then, the basis of moral sentiment with which the voice of conscience is indissolubly associated. A non-gregarious animal can do what it likes; it has only itself to consider.

Antagonism of Herd and Personal Instincts.

There is a fundamental difference between this herd instinct and the personal instincts of self-preservation, nutrition, and sex. These are dependent on the impulse of the moment; but the herd instinct is a controlling force from without, which is perpetually acting in antagonism to the other three. The child is taught from the cradle to respect the feelings of its companions, to resist its own impulses in order to protect others, to comply with their desires, and not to be selfish or greedy. And when the sexual passion asserts itself he finds that it is antagonised by a very strict code of conduct, with which it becomes his instinct to comply. Not only must such a passion be denied free play, but he must never allow his genitalia to be seen, and he must not discuss sexual topics or even think about them. The whole subject of sex is taboo, and this is one of the chief reasons why psycho-analysis has encountered severe antagonism. For a long time gynaecology was in the same position for a similar reason.

We find, then, that it is instinct which governs the whole of our mental life. Instinct is no more and no less than "psychical energy," the driving force of mentation to which Jung has applied the name "horme." This word "horme" has a wide signification, applicable to all the instincts, and corresponds with the word "libido" in reference to the sexual instinct. "Horme" means psychical energy, desire plus a conative trend. In short, I conceive it as being more or less synonymous with instinct, the driving force of our mental life. Every individual is endowed with a certain quantity of horme. Sometimes it is active in one direction, sometimes in another; it is never quiet. Comparable to physical energy, which may display itself as movement, sound, heat, light, electricity, or chemical action, it is never lost, and the principle of the conservation of energy is to be regarded as equally applicable to both psychical and physical energy. If a certain amount of horme or psychical energy in a given patient appears to be lost, it becomes our duty to discover where it has gone; but I will return to this subject later.

There is, as I have just suggested, a constant play between the instincts, one giving place to another as occasion arises; but when a herd impulse becomes displaced by the driving force of some other instinct mental conflict ensues; there is a situation to be faced, and a way out of the difficulty must be found. "Twixt love and duty" has always been a favourite theme with artists, novelists, poets, and philosophers. If duty fails—that is to say, if the herd instinct fails—some way must be found to pacify the guilty conscience.

The conflict may be resolved in one of four ways: First, the influence of the herd instinct may be recognised and its influence voluntarily ignored, the delinquent avowing to himself that he has a perfect right to do as he likes. The herd instinct is so strong that this process is, as a rule, difficult; but everybody knows that such unscrupulous persons undoubtedly exist.

Secondly, the offence may be condoned by "rationalisation," the offender excusing himself on the ground that he is otherwise a very good fellow. He goes to church regularly, subscribes to the charities, and is a good patriotic citizen, the logical fallacy here being, of course, the *ignoratio elenchi*.

Thirdly, the emotional tone or affect of worry may gradually pass off as years roll by, and he becomes occupied with other matters, in just the same way as we do not feel after the lapse of time the loss of a dear friend to the same extent as when we first hear the news of his death.

And lastly, the incident may refuse to become assimilated to the existing content of consciousness and be forgotten. The memory is banished from consciousness, but this does not mean that it is banished from the mind. It means that an attempt is made to repress it into a department of mentation from which it can never again enter phenomenal consciousness and disturb the normal stream of associative thought. Later on we shall have to discuss what happens should this repression subsequently fail, as it very frequently does.

THE UNCONSCIOUS.

This brings me to one of the fundamental bases of Freudian psychology—viz., the conception of the unconscious. At any given moment during a stream of thought there are only one or two ideas present in phenomenal consciousness. Under certain conditions in the psychological laboratory it is possible to demonstrate that as many as six or seven ideas may be present in consciousness at the same time, but in practical thought seldom more than two ideas occupy the field of attention. In close association with these ideas, however, at what is sometimes called the fringe of consciousness, but outside the field of attention for the moment, there is a much larger number of percepts, ideas, and other mental states. These have been grouped together for practical purposes and called the "subconscious." There still remains a large number of ideas and memories quite outside the field of attention, but capable of recall when required. These are known as the "foreconscious" or "preconscious."

Now there is an enormous number of ideas of past experiences, incidents, and situations which we cannot by any possibility remember, no matter how hard we try. For these there is a life-long amnesia. Nevertheless, they are not lost. They sometimes flash into the mind in moments of abstraction and during dreams; it is said that they are all passed in review during drowning, and they can be recovered by such artifices as hypnotism, crystal-gazing, and psycho-analysis. This group of ideas is called the "unconscious." The name is perhaps a little unfortunate, because "unconsciousness" has nothing to do with these phenomena, which were recognised in this country long before Freud's day and were described as "unconscious cerebration." I believe that the name was then the chief reason for their non-acceptance, for it was rightly contended that "unconscious cerebration" is a contradiction in terms. If hybrids were tolerated I would suggest some such name as "hypoconscious" for such mental states. It is not usually pretended that every incident that has ever happened in our lives is conserved in the unconscious (although Bergson says this), but it would certainly be true to say that all experiences which have been accompanied by a strong affective tone are conserved, even right back into early infancy.

PSYCHICAL DETERMINISM.

Another fundamental doctrine of Freudian psychology is that of "psychical determinism," which postulates that every mental process is predestined and fore-ordained. According to Jung, such predestination is due to the conscious activity of a higher power, God or world consciousness; but Freud ascribes it to an unerring scientific law of causation.

While recognising that there are certain characteristic tendencies and reactions, physical and psychical, common to all mankind and given to us by heredity and evolution (the inherited instincts already mentioned), we must also take into account the fact that the experiences of every one of us differ from those of all other people. Instinct is the driving force which causes A and B to act in the same way when confronted with a given situation, but their thoughts and actions in association therewith are differently carried out because their individual experiences are entirely different. These and other considerations, to be discussed presently, led Freud to the study of "individual psychology," one outcome of which has been the enunciation of the doctrine that for every psychic fact there have been efficient and logical antecedent causative mental states in the present life-history of the individual, and that there is a continuity of mental associations from the cradle to the grave. In other words, there is no such thing as chance in the determination of a thought.

To take a favourite example. Suppose I ask you to think of a number and you take the trouble to investigate your particular association with the number selected, you will find that the number has some relationship with an item of your experience associated with the present content of your consciousness. Under the circumstances no other number could have occurred to your mind; the mental process concerned is absolutely governed by the laws of association of ideas.

COMPLEXES.

The number is one unit of a constellation of ideas, another unit of which is one idea now present in your consciousness. When such a constellation is repressed and partly unconscious it is known as a "complex." I give a few examples to make my meaning clear.

While preparing these lectures, any patient exhibiting a good example of mental processes I am now endeavouring to explain caused me to think of the Morison lectures, as also did mannerisms of people I met in the street, certain items of information in books, thoughts of the unconscious motives of war and incidents of psychological interest on the battlefield, papers read to less distinguished audiences, mental facts in my own life, and a host of other things. In other words, I have had a "Morison lecture" constellation of ideas. It has not been repressed and should therefore not be called a complex.

I meet a man in the street who at one time did me considerable injury by reason of certain jealousies, &c. He is the centre of a number of ideas of difficult situations and incidents which caused me perplexity at the time, but are now repressed and partly forgotten; but I feel vexed when I see him. This is one of my complexes.

A favourite example is that of a young man in love. His emotional state tends to constellate all his ideas to the one central figure, his lady-love, no matter how remote the association may be. The

act of writing at his office desk reminds him of writing to his adored one, a luxurious motor-car makes him think how she would look in it, a chance resemblance causes him to wonder "Is it she?"; the sermon at church contains many allusions to his love for her, and all nature echoes his happiness. It is the "love" constellation or complex.

In fact, the whole of our unconscious mind is made up of complexes, and the total mass of these taken together constitutes the "ego complex." A complex, then, may be defined as a repressed system of ideas having a constant conative trend or emotional tone and directed towards determinate actions and thoughts. A complex is therefore possessed of a certain amount of energy, and since complexes can generally be referred to some instinct we may regard this energy as a manifestation of the hormone we have already discussed. The liberation of this energy by discharge, either by an outburst of emotion or by the fulfilment or realisation of the conative object of the complex, is known as "abreaction." Abreaction of the love complex, for example, is the possession of the desired object of affection.

CONFLICT.

We are now in a position to consider in rather more detail the phenomenon of "conflict." When there develop in the mind two complexes which are out of harmony with one another, and mutually repel or paralyse each other, conflict ensues. A hypothetical instance of conflict between two nutrition complexes is given in the fable of the animal which died of starvation when, suffering equally from hunger and thirst, it found itself midway between a basket of food and a pail of water. Conflict occurs between two self-preservation complexes when a man finds himself stranded on the High Alps, when inactivity means death from starvation, and an attempt to reach the valley threatens death from precipitation. Conflict arises when a man finds he has fallen in love with two women at the same time. But conflict never arises between a nutrition complex and a sexual complex, or between a self-preservation complex and a nutrition complex, unless, of course, the nutrition complex is so urgent (as in the above instance) that it constitutes at the same time a self-preservation complex. Conflict between a sexual complex and a self-preservation complex is fairly common, and either may win, as in the question of plunging into a marriage which is inimical to one's life interests or facing death to save a loved one from danger.

In practical experience, however, we find that by far the greater majority of conflicts occur between a personal complex and a herd complex—that is to say, between morality, religion, ethics, or fashion, on the one hand, and nutrition, self-preservation, or sex on the other. Now the only ways in which nutrition complexes and self-preservation complexes can conflict with the herd instinct are by such crimes as murder, theft, and dishonesty; but there is only one way in which satisfaction of the sexual instinct does not conflict with the herd instinct—viz., by legitimate wedlock. Masturbation, homosexuality, adultery, incest, fetichism, sadism, exhibitionism, and bestiality, many of which are exceedingly common, are all under the ban of the herd; and as a matter of practical experience by far the majority of conflicts, which we find on psycho-analysis to lie at the root of the neuroses and psychoses, are between a sexual and a herd complex.

Now a conflict cannot be allowed to persist for ever. It is a biological necessity that some way out of the difficulty must be found. The normal and logical way out of the situation is to face it, to recognise that there is a conflict, to consider what is the right and proper course to pursue and to take that course, at the same time admitting to oneself that such a conflict has existed.

Evasion of Conflict.

If, on the other hand, the victim refuses to face the situation and attempts to evade it, this may be done, as I have already mentioned, in one of four ways.

First, he may recognise the influence of the herd instinct and refuse to be guided by it. In my experience this is, as a rule, not very successful. The herd instinct is a true instinct and refuses to be repressed, with the result that the patient suffers from remorse, usually accompanied by an unexplained headache and other neurasthenic symptoms which are very difficult to dislodge.

Secondly, he may seek refuge in "rationalisation," keeping his conflicting personal complex in a "logic-tight compartment" of the mind. The swindling financier refuses to acknowledge to himself that he, as a financier, is the same individual who reads the lessons at church and built the local almshouses, or he condones his swindles with acts of piety and charity. This is an example of what is known as "dissociation" or, as Janet calls it, the "splitting of consciousness." This phenomenon occurs quite commonly when, for example, we converse on one subject and write a letter about another, and it is quite possible for our financier, while reading the lessons, to be at the same time devising some scheme whereby he may succeed in transferring somebody else's banking account to his own.

In pathological domains we observe a similar splitting of consciousness in the general paralytic who, while believing himself to be God Almighty, begs his attendant for a cigarette, or in the asylum queen who is elated in being the chosen patient to wait on the nurses. Dissociation occurs also during the "automatic writing" of certain hysterical patients. If such a patient be given a pencil and a piece of paper and be held in conversation while a third person whispers questions into the patient's ear, she will correctly answer the questions by writing, all the while being unconscious of the fact that she is writing.

Another variety of dissociation occurs in the cases of "double consciousness." Here the patient has two entirely different personalities, each being independent and unaware of the existence of the other. Robert Louis Stevenson has dramatised the condition in the familiar play "Dr. Jekyll and Mr. Hyde," and I need not quote the well-known case of the Rev. Ansel Bourne, reported by James and Weir-Mitchell. Marandon de Montyel placed on record the case of a man who remembered nothing between being about his business in Paris and returning to his normal personality on board a ship bound for Bombay. Records of many similar cases are to be found distributed throughout the literature.

Thirdly, our victim of conflict may allow the energy of his complex to be diverted into other channels than the natural one. This process is called "sublimation," and the best examples are again to be found in the domain of sex. The old maid has at one time been possessed of a sexual instinct quite as strong as that of her married

sisters, but its natural outlet has been denied her. What outlets can she find for her pent-up energy? She devotes much to dress, which is often extravagant, or she indulges in all sorts of gaieties, or she takes to nursing, or, by a kind of transference, she interests herself in society news, especially of the type to be found in so-called "society newspapers," and she loves to read the details of marriages and scandals. Moreover, her maternal complex has to be satisfied, and she reads the columns of births daily and bestows her maternal affection on cats, dogs, and parrots.

A man may sublimate his sexual instinct into dangerous sports. In the early days of aviation, when it was much more dangerous than it is now, an acquaintance of mine took to this sport when the circumstances of his marriage became somewhat distressing. Sexual sublimation in men also takes the form of academic interests, increased professional activity, travel, collecting manias, and alcoholic excesses. For reasons which need not be discussed for the present Freud regards smoking as being frequently a sexual sublimation; but I am sure that it is a common sublimation of other complexes.

Sometimes sublimation takes the form of inversion or representation of the opposite. The old maid, for example, often betrays her sexual complex by extreme prudery or by devoting herself to excessive religious exercises. Displacement of masturbation usually takes the form of the victim handling his body in other ways, such as nail-picking, nail-biting, or nose-picking; but these should not be called sublimations, because this term always means diversion to useful social aims.

Fourthly, lastly and most important of all, the conflicting personal complex may refuse to become assimilated to the normal content of consciousness and become forgotten. Perhaps a better way of putting this is to say that the victim refuses to admit to himself that such a complex ever existed. The popular way of expressing this is to say that he "puts it out of his mind," but what really happens is, as we shall see later, that he puts it into his mind, pushes it in deeper into the unconscious or, as we say technically, "represses" it. This is the phenomenon of "repression," really another form of "dissociation" or "splitting of consciousness." It differs, however, from the previously discussed variety in that a complex dissociated by repression has an autonomous existence. There is a constant resistance against the elements of a repressed complex becoming associated with those of phenomenal consciousness. This resistance, which is nothing more than a continuation of the original repression, is called by Freud the "censor," and has been personified by his English and American translators into the "censor."

Results of Repression.

Now it is clear that it must be a very difficult matter for the normal train of thought to proceed year in and year out without once touching upon some idea which tends to become associated with some element of the repressed complex. Such ideas and other mental states are bound to occur, and since the "censor" will not allow repressed ideas to enter consciousness, the only possible alternative is that conscious ideas become anchored to the unconscious complex. The result is that the unconscious tends to grow at the expense of the conscious; and it may be taken as a rule that the greater the emotional tone of the original complex

the greater does that complex grow when it becomes unconscious. The fact that the unconscious grows constantly at the expense of the conscious explains why a case of long duration takes so much longer to cure than a case of recent onset.

"Dissociation" and "repression" are closely allied to one another, and it will also be observed that "sublimation" usually involves "repression." The old maid's prudery is an obviously successful method of repressing her sexual complex, and her fondness for domestic pets subserves the repression of her maternal complex.

It is not to be supposed that sublimation and repression are usually pathological or abnormal. On the contrary, they take place to an enormous extent in the earlier years of us all, and play an important rôle in early education whereby our naturally vicious animal energies are repressed into the unconscious and sublimated into useful activities. It follows that our unconscious consists for the most part of infantile complexes, and this accounts to some extent for the amnesia which veils the first years of childhood. It is true that this amnesia is partly due to the fact that many of the cerebral neurons are not yet myelinated, but that this is not the only reason is evidenced by the fact that the amnesia is here and there broken by isolated memories of unimportant incidents. Freud has called these "cover-memories" because they serve to displace memories of important events.

When these repressions or sublimations for any reason fail we have the conditions necessary for the development of neurosis or psychosis, conflict occurring between the repressed complex and the existing content of phenomenal consciousness. Under such circumstances the complex escaping from repression is distorted and disguised by way of an attempt to render it acceptable to consciousness, and its distorted manifestations constitute the symptoms of the disease. Solution of the difficulty and cure of the disease are accomplished by revealing to the patient through his own association mechanisms the full content of the repressed complex. How this is to be done I will explain in my next lecture.

I have already mentioned that complexes related to the sexual instinct are repressed more than any other. It is therefore not surprising to find that these play an enormous rôle in the psychoses, and a knowledge of the development of the sexual instinct is so essential to any comprehension of the new psychiatry that I must discuss this matter in some detail. I ought to say that this knowledge has been gained, in the first instance, entirely through psycho-analysis.

THE SEXUAL INSTINCT.

Those members of my audience who have devoted their attention to the study of disease in children, especially nervous disease, will be the first to admit that sexuality is not a function which suddenly springs into being at puberty, but that it gradually develops from small beginnings in the earliest infancy. Freud considers that sucking the mother's breast is partly a sexual act, but Jung dissents from this view and considers the act of sucking the breast to be purely nutritive in function. Both these leaders of thought agree, however, that thumb-sucking, which follows shortly afterwards, is of undoubted sexual import, and many shrewd mothers are independently capable of discerning masturbatory significance in this common infantile action. Indeed, any action in

which the child habitually handles the body, such as nose-picking, nail-biting, or rubbing its abdomen, is to be regarded as betokening a masturbation complex.

Now in adult life many of the sense organs are capable of stimulating the sexual instinct: for example, the eye (in seeing a beautiful face or figure), the ear (in hearing a beautiful voice or the rustle of a dress), the nose (in sensing certain odours characteristic of the opposite sex), and the skin (in feeling the skin of a member of the opposite sex, or even, with some people, experiencing a sense of pain); but the centre of maximal stimulus is the genital organ. In the child, however, there is no centre of maximal stimulation to be discovered, the pleasure-arousing area being equally diffused all over the body, and therefore so much the less stimulating in any given zone.

Erogenous Zones.

Freud has discovered, however, that even in the young child there are certain areas the irritation of which produces greater gratification than elsewhere. Although these lie at the foundation of the sexual instinct, it is not suggested that the child himself has any idea of the nature and significance of these sensations. These areas, which I am about to mention, have been called by Freud the "erogenous zones."

I have already referred to the mouth. Freud and others discern something of the nature of an orgasm when a satisfied baby becomes flushed, leaves the breast, and sinks into slumber. It has also been observed that thumb-suckers are liable to manipulate or rub their breasts during pleasure-sucking, and this is said to be the first step towards masturbation. Energetic suckers in infancy are said to be very fond of kissing when they reach adult life and, if at any time the complex becomes repressed, there are produced such symptoms as hysterical vomiting, aversion from eating, hysterical globus, choking sensations, snoring in the throat, and disturbances in eating. These are some of the arguments used in support of the view that the mouth is an erogenous zone, and some of the symptoms suggest that Freud is right in his view that breast-sucking for the purpose of nourishment is partly of sexual import. It is at least obvious that the first sensory stimulus the mouth receives is from the mother's breast, and our other considerations suggest that the baby's mouth should not be stimulated more than is necessary for purposes of nutrition. This is an argument I have not previously heard against the use of "dummies" or "comforters."

Another important erogenous zone lies at the other end of the alimentary canal, the anus. It is often observed that the "intestinal catarrhs" of infancy give rise to "nervousness," but the erogenous significance of the anus is noticeable in children who voluntarily retain their faeces until violent muscular contractions necessitate compulsion. The pain caused by the passage of the larger accumulation is accompanied by a pleasurable sensation which the child seeks to experience again. It is a variety of masturbation. This habit, which is a sure premonition of subsequent eccentricity or neurosis, plays an important part in the production of the constipation so common in neurotic patients, and Ernest Jones has recently shown that it lies at the foundation of the sadistic complex which is responsible for the compulsion neurosis. Incidentally I may mention that a large

number of such patients have private secret customs and ceremonials of their own which they habitually observe when they retire to evacuate their bowels. People who have succeeded in repressing the complex become in after life methodical, thrifty, and headstrong. It would appear that the desire to retain faeces becomes sublimated into the desire to retain money, and those of you who have had experience of psycho-analysis know how commonly in the neurotic "faeces" symbolises "money."

The third erogenous zone is the neck of the bladder. Freud has discovered that whenever enuresis nocturna is not caused by epilepsy it represents a pollution corresponding to a sexual dream. It may, of course, have its physical causes, such as adhesion of the prepuce, but that does not affect the main question. It is not commonly apprehended that bed-wetting is a source of gratification to the infant. Bed-wetting in childhood plays an important rôle when neurosis develops in after life.

The fourth erogenous zone is the inner surface of the thighs. Pleasure experienced by rubbing the thighs together is often to be observed in quite young infants, especially females.

Even in the earliest years, therefore, there is a tendency for such pleasurable sensations to be localised in the neighbourhood of the genital area, and Nature appears to have made special provision for their periodical excitation by uncleanness and consequent cleansing.

Later Periods.

The period we have been discussing is characterised by the infant finding a kind of gratification in the stimulation of parts of its own body. About the third or fourth year, however, the whole of this infantile sexuality becomes repressed by education and by the development of feelings of shame, loathing, disgust, and morality. It is during this stage of repression, the "latency period" as it is called, that the infantile germs of sexuality become sublimated and applied to refining, cultural, and social ends; but should misadventure or adversity befall this sublimating process, the child is destined to become the victim of neurosis.

From the fifth or sixth year onwards, in what Jung has termed the "pre-pubertal period," we begin to observe a recrudescence of sexuality, but it differs from the first period in that the child now strives to come into closer relationship with the outside world. The first was a period of "subject love" or auto-eroticism; this is a period of "object love," and the child seeks to love somebody other than itself. Naturally the first object of its affection is the person with whom it is brought into closest relationship—viz., the mother or the nurse. This is, of course, due to a feeling of dependence, and is therefore very strong. Even as early as this we can discern some psychical differentiation between the sexes, for the boy's love is mostly directed towards his mother and the girl's towards her father. It is also to be noticed that a boy loves his sisters more than his brothers, and a girl loves her brothers more than her sisters. Even childish love affairs with others are of greater significance than is usually thought. It has been erroneously supposed that fixation of a boy's love on his father or a girl's love on her mother, during this undifferentiated period, laid the foundations of inversion or homosexuality, either manifest or unconscious; but psycho-analytic

experience gives no support to this view. On the contrary, it is found, curiously enough, that inversion arises from fixation on and identification with the parent of the opposite sex, as I shall explain presently.

Sexual Perversities.

The child's sexuality at this stage is, as Freud has termed it, "polymorphous-perverse," and untoward incidents are liable to direct his instinct into wrong channels. Encouragement of the natural tendency to undress before others may lead to exhibitionism; the habit of inspecting one another's genitals, if opportunity is allowed, may lead to the "peeping tendency" and desire to see the genitals of others, especially of their elders. Such curiosity begets an aggressive disposition, which in turn serves as a groundwork for the sadistic instinct, whose special feature is the association of cruelty with the sexual impulse. Masochism, in which the sexual impulse is aroused by certain experiences of mental or physical pain, can most often be traced to punishments inflicted during childhood.

Inversion or homosexuality arises in this way. It is normal for the child to develop curiosity respecting sex and birth processes. Indeed, it is only natural that he should want to know where a new brother or sister comes from, for such a person threatens to displace him and to absorb the love of his mother which has previously been lavished on him. He is jealous; but this is a digression. The normal boy imagines all people, including his mother, to be fashioned like himself in every detail. Accordingly, if the time when he is disillusioned arrives too late, when incest barriers demand that his affection should be transferred elsewhere, he can only fall in love with a person fashioned like himself. Such individuals, therefore, seek as cohabitators either boys or effeminate men. Girls who develop the converse phantasy become homosexuals in a similar way.

As I have just hinted, the normal change which takes place at puberty is the erection of incest barriers, whereby the love for the parents becomes gradually weakened as the adolescent becomes attracted to persons of the same age but of the opposite sex. I say "of the opposite sex," but it must be remembered that the sweetheart is of the same sex as the child's first love. Moreover, the parents usually serve as an unconscious pattern for the mates of young people. Boys have a natural inclination to some girl resembling their mother, and girls to some boy resembling their father.

There are some individuals who linger over intermediate sexual attractions so that their libido becomes permanently fixated on these instead of passing them over rapidly on the way to an ultimate sexual goal. Such a condition is known as fetichism, and the victims are fetichists. They find an ultimate sexual goal in seeing or feeling the hand, foot, or hair of a woman, or in hearing her voice, or their libido becomes fixated on some impersonal object, such as a shoe, a handkerchief, fur, velvet, &c.

When these perversities are manifest to any given person and self-avowed they do no harm to his nervous system; indeed, many perverts have shown themselves to be of exceptional intellectual ability. Voltaire has confessed to systematic masturbation, Rousseau was an avowed masochist, and it will be easy for you to recall the names of homosexuals of great ability in professional directions; but when such perversities are repressed in an individual he constantly runs the risk of

neurosis through his repressed complex escaping the repression. If, for example, a repressed homosexual—that is to say, a person who has developed unconscious homosexual tendencies and does not know it—gets married he is almost certain to develop neurosis or psychosis.

Now when conflict arises between a repressed complex and phenomenal consciousness—in other words, when an unconscious complex strives for recognition, and consciousness, or perhaps I ought to rather say subconsciousness, endeavours to maintain the repression—neither one nor the other achieves success, and the result of the conflict is a compromise, this being none other than a symptom or group of symptoms of neurosis or psychosis. The discussion of the various mechanisms which come into play in this process I will postpone until the consideration of dreams in my next lecture, for the mechanism of dreams is almost exactly the same as that of the insanities. We shall find that, in its attempt to escape repression, a complex becomes distorted and disguises itself in such a way that its true nature is not revealed to consciousness.

Nature of Infantile Complexes.

Some of the infantile complexes to which I have referred will still remain somewhat obscure unless their nature is fully apprehended, and I must revert to the relationship between parents and children as it is unconsciously conceived by the child. As I have already submitted, the mother is the boy's and the father is the girl's favourite parent. Now this means a great deal more than appears at first sight, for it has been established from the study of children and from the dreams of adults that the boy's love for his mother is of such a character that he resents sharing his mother's love with anyone else, especially the father. A very large number of boys ask their mother at some time or other whether she loves him or "daddy" the more, and the child usually receives (quite rightly from an educational point of view) a disappointing answer. The boy is jealous of his father and, similarly, the girl is jealous of her mother. Each, in fact, wishes the parent of the same sex out of the way, and may go so far as to dream of the death of this parent. We shall see in the next lecture that a dream is the realisation of a wish.

This incest complex, which exists in the unconscious of every individual, normal or abnormal, is known in the case of a man as the *Œdipus complex*, and in the case of a woman as the *Electra complex*. *Œdipus* was a king of Thebes who had the misfortune to slay his own father and unwittingly to marry his mother. *Electra* was the daughter of *Agamemnon* and *Clytemnestra*; she assisted in the murder of her own mother to avenge the death of her father.

In a very large number of cases it can be demonstrated by psycho-analysis that such complexes play an important part. We expect to discover it especially in patients who, in spite of normal heterosexuality and in spite of encountering many opportunities of, and even calls to, marriage, have reached middle age without having engaged in matrimony. This is especially to be found in only children, whose fixation of libido upon their parents is exceptionally difficult of transference elsewhere, and whose parents tend to foster the delusion that there does not exist in the wide world a suitable mate for their darling child.

LOW LEVEL OF THE UNCONSCIOUS MIND.

The conclusion at which we have arrived from all these considerations is that our unconscious mind is on a lower, less mental, more neural, and more animal plane than our conscious mind, and it is pervaded with sexual thoughts and desires. Indeed, I believe that I am not misrepresenting Freud when I say that he thinks that the unconscious mind is almost all sexual; but then it must be recognised that he uses the word "sexual" in a very wide sense. Attraction, friendliness, shame, modesty, and disgust are all included under this term by Freud. Nevertheless, psycho-analysis has revealed that if our repressed mental material had free play, uncontrolled by consciousness, every one of us "would probably remain a selfish, impulsive, aggressive, dirty, immodest, cruel, egocentric, and conceited animal, inconsiderate of the needs of others and unmindful of the complicated social and ethical standards that go to make civilised society."¹

To the ordinary man whose "herd instinct" has repressed such intolerable features of his character into the unconscious and converted him into a moral, social, ethical, modest, and æsthetic being, it is incredible and absurd that his mental constitution and disposition are fundamentally so brutal. He is prepared to accept the fact that his anatomical and physiological characteristics are identical with those of the lower animals; but his mental characteristics—never! And so from time to time we find in the medical journals energetic objections to our new psychiatry, of course by people who have not studied it. These letters are interesting examples of what is technically known as the "resistance," which we shall study in our next lecture, and are unwitting arguments in support of Freudian doctrines.

In the *Medical Press and Circular* for June 13th, 1894, is to be found a paper by the late Dr. Hughlings Jackson, entitled "The Factors of Insanities," and it will be there seen that that great man foresaw the fundamental principles of our new psychiatry. He pointed out that there is a positive and a negative element in every case of insanity, the negative being defect of consciousness or loss of some consciousness, the positive being activity of the consciousness remaining (on a lower level). For example, when a patient believes himself to be the Emperor of Europe, Hughlings Jackson points out that the chief defect (negative element) of consciousness is that he does not know that he is a clerk in the City, and the notion that he is the Emperor of Europe is due to the positive activity of a lower level of mentation. This is exactly what has been proved by our modern school of psychiatry. So far as consciousness is concerned, we know that it always loses something of its content, a complex which is repressed into the unconscious, while the positive symptoms of an insanity are due to the distorted activities of the unconscious (a lower level of mentation). While, therefore, we study and admire the insight and patient labour of the great Austrian psychologist, Professor Freud of Vienna, let us at the same time pay homage to the great English father of neurology, who taught us to understand the nervous system, Dr. Hughlings Jackson.

Sir Alfred Pearce Gould has presented to the Middlesex Hospital the armchair used by the late Lord Lister during his last illness.

FROST-BITE IN THE PRESENT WAR.

By C. MAX PAGE, M.S. LOND., F.R.C.S. ENG.,
CAPTAIN, R.A.M.C. (S.R.).

THE term "frost-bite" has been applied to a condition which during the past months has led to the invaliding of a large number of our troops. That the term is an unsatisfactory one must be admitted, for a large percentage of the cases result from exposure to wet at a time when the temperature is above freezing point. None the less, as the same condition may be produced by frost, it would only be confusing to alter the nomenclature. On the Turkish side in the late Balkan War, before any frost had set in, the incidence of a condition allied to frost-bite was noted.¹ The fact that extensive gangrene was common was presumably due to the poor nutrition of the men and the inadequate medical organisation. The same statements are true for a certain period of the Crimean War.²

As in spite of prophylactic measures a certain incidence of the condition may be expected for a month or so yet, it seems worth while to note the phenomena of the condition as seen in a Base Hospital in France, and quote the results of treatment hitherto adopted. Some 332 cases classified as frost-bite have passed through this hospital (No. 2 Stationary). The majority of the cases have been sent on to England after being under treatment here for a few days; but systematic observations were made on 30 average cases over a period of two to three weeks, with a view to determining the period of invalidity and the results of various forms of treatment.

Examining the whole series of cases, in only 5 was macroscopic gangrene present. As the treatment and course of the disease in this class of the condition are well defined it will not be referred to in these notes. In all cases both feet were affected, usually with about the same severity. In only 2 cases were the hands involved as well.

General Etiology.

The cases give a consistently regular history of exposure in wet trenches for periods varying from 24 to 72 hours. The weather is said to have been cold, but frost was said to have been present in only about 10 per cent. of the cases. The nutrition of the subjects has been good, and in no case have they been starved. In most cases nerve-strain and lack of sleep have been factors which may have had an effect. As a rule the cases exposed to frost after wet have shown the most severe lesions.

Pathology.

The actual process rests upon surmise, but appears to be as follows. The capillary circulation is slowed by surface chill. At the same time the general circulation is sluggish from bodily inactivity. Prolonged standing promotes blood stasis in the feet, and in some cases may be a concomitant factor. This stasis damages the capillary wall and exudation takes place. This will tend further to check the blood-supply to the feet, and in severe cases leads to gangrene of a greater or less part of the foot.

If this swelling occurs while the boot is still on the skin is exposed to pressure. This pressure produces the sensory changes which are noted below. This latter statement is supported by the following observations: 1. When the hands are involved the type of anæsthesia seen regularly in

¹ Gangrene in War, British Medical Association, July, 1914.

² Ibid.

the feet does not appear. 2. In cases of any severity the skin of the toes, being limited and tight, always becomes anæsthetic. In cases of moderate severity with anæsthesia of the dorsum of the foot the skin under the instep often remains sensitive, it being the part of the foot least exposed to pressure from a boot. 3. If a man's foot be covered with lint or a sock and then firmly bandaged from the toes upwards with a Martin's rubber bandage and so left for three or four hours, anæsthesia of the skin of the toes and neighbouring part of the dorsum of the foot sets in and persists for a day or two.

Clinical Signs.

Excluding instances of gangrene, three types of case may be defined: 1. Where there are no signs to the naked eye, but where anæsthesia of the functional type is the prominent feature. 2. Where there are no signs beyond slight œdema, but where organic sensory changes are found. 3. Cases where in addition to organic sensory change there are gross œdema and bleb formation. These three types, it will be seen, are not pathological entities and may overlap, but they are useful as a basis upon which to form a prognosis.

The signs and course of these three classes of the condition may now be considered in more detail.

Type I.—This usually appears in young men either nervous or sullen in mien. To general observation there are no objective signs. They walk poorly, keeping the weight on the heels; the gait often improves when they do not know they are under observation. On testing sensation with the point of a pin anæsthesia will be present, sometimes to a level 5 or 6 inches above the knee. The upper margin of anæsthesia is sharply defined and of the "stocking" type; loss of sensation to wool is present over exactly the same area. The level of the anæsthesia is liable to vary if successive observations are made on the same day. Pressure sensation is absent, and the subjects will say they do not know the foot is being touched, even when movement of the whole limb has been involved. The reflexes are normal or slightly diminished. Voluntary movement of the toes appears to be impaired. If such cases are treated with the faradic current the anæsthesia rapidly disappears (often after one application in this series). It may then be found that a condition indistinguishable from that of Type II. persists. The only difference in the subsequent course of the case is that these patients tend to complain of subjective sensations in the feet to an exceptional degree. Four cases of this class were noted in 30 consecutive cases, and I think the incidence for the bulk is about the same. It will be seen that the prognosis must depend mainly on the degree of organic disease present. As stated, it is usually slight or even negligible. On the average, with firm treatment, these cases are fit for duty again in from 7 to 14 days.

Type II.—The only objective sign in this type is slight œdema, which on admission can usually be noted below the ankles. This swelling commonly disappears after 24 hours' recumbency. In all cases the subjects state that their feet were swollen at the time of onset of the condition. On testing the sensation with a pin anæsthesia over the dorsum of the toes is constantly present; it commonly extends on to the dorsum of the foot for 2 or 3 inches, and may extend to the level of the ankle-joint. The thin skin of the sole is sometimes sensitive, sometimes anæsthetic. On testing with wool the area insensitive to light touch

corresponds with, but is not quite as extensive as, the area of anæsthesia; there is definite loss in the acuteness of sensibility in the marginal zone. Sensation to deep pressure is normal. As the cure progresses the depth of the anæsthesia lessens, till in a week or less it is limited to the dorsum of the toes; contemporaneously sensibility to light touch recovers much more rapidly. At the end of a week some degree of hyperæsthesia may develop and persist for a few days. During this period various types of pain in the feet, ankles, and calves may be complained of. On admission voluntary movement of the toes is weak, and unless the feet be massaged this condition may persist for a couple of weeks. The toes often appear to be kept slightly dorsiflexed. In the hyperæsthetic period passive movement of the toes is usually painful. From half to two-thirds of the average cases are of this type. In the series of 30 noted 19 of this type were recorded, and 9 of them were fit for discharge from hospital in about 14 days.

Type III.—The objective signs are well-marked—œdema, bleb formation, and ecchymoses. The œdema is most prominent over the dorsum of the foot and below the malleoli, but it may extend two-thirds of the distance up the leg. After a few days in bed the major part passes off, but some swelling about the external malleolus may be present for a fortnight. The blebs are usually on or near the toes, and may contain blood. They seldom become infected if snipped and evacuated at an early stage. Small petechiæ may be seen at the bases of the nails in many cases. The sensory changes are similar to those seen in Type II., but in general are more extensive; anæsthesia over the whole area covered by the boot may be present for a day or two. Recovery seems to be rather slower than in Type II., but shows the same difference between anæsthesia to the pin and loss of sensibility, both conditions being thus clearly separable from the condition in Type I., which presents a typical functional anæsthesia. These cases almost all develop a stage in which there are marked hyperæsthesia of the skin and pain on moving the toes. At this time the skin is hyperæmic, and the foot feels hot as a whole. This hyperæsthetic stage comes on in about one week from the commencement of the attack, and may persist for another. The loss of movement in the toes is similar, but more marked and persistent than in Type II. Seven cases in 30 were of this variety. No case was really fit for duty within 18 days, the limit of my observation in these cases.

Treatment.

The classical treatment of frost-bite is mainly directed to obtaining a moderate general circulatory reaction in the part affected. In the class of the condition under consideration there is no failure of return of circulation, and efforts are directed to procure a rapid convalescence and relieve the subjective sensations. In this series treatment of various kinds has in symmetrical cases been applied to one foot only. The control foot has been cleaned up with spirit, dusted with powder, covered with wool, and then left to itself. Blebs if present were snipped and emptied of their contents.

Active treatment may be in the nature of: (a) curative, and (b) symptomatic.

(a) The curative methods tried were all local; no drugs (excepting calcium chloride) having a general effect in the capillary circulation were given. The rationale of these local methods is to improve the nutrition of the foot by promoting the capillary

circulation. Four types of agent were employed—viz.: 1. Counter-irritants: tincture of iodine, oil of turpentine, and liniment of camphor. The lotions were applied on lint and the foot covered with wool and loosely bandaged. 2. Production of hyperæmia by physical means: hot fomentations, hot baths, and Bier's congestive bandage. Hot-air baths would seem the soundest method, but are not readily available under service conditions. 3. Massage. 4. Electrical stimulation: the faradic current alone was used.

Results of curative methods.—1. None of the counter-irritants above mentioned appear materially to affect the speed of recovery, either in relation to the disappearance of the anaesthesia or return of movement in the toes. All of them inconstantly relieved pain for a short period, and for a time proved comforting. Oil of turpentine frequently produced vesication, and was always followed by desquamation of the skin of the foot. The same is true of tincture of iodine in a less degree. This desquamation may be so severe that in slight cases the tenderness of the newly exposed skin prolongs convalescence after the primary condition is cured.

2. Hot baths (half an hour twice daily at 105° F.) in two cases definitely expedited the appearance of hyperæsthesia. The treatment could not comfortably be continued after its appearance. Hot fomentations are similar in their effects, but are liable to render the skin sodden. Congestion by rubber bandage was applied for one hour twice daily in cases without oedema. It did not appear to influence the course of the disease in either direction. In two instances it was applied for three or four hours at a time and relieved deep pains for a few hours afterwards. This application frequently produced fine ecchymoses in the foot and leg.

3. Massage in all cases in which it was tried accelerated the onset of hyperæsthesia. At this stage it could only be continued if most delicately applied. In all cases nearing the convalescent period it improved the movement of the toes, and so hastened effective recovery.

4. Stroking the legs and feet with the electrodes through which a faradic current was passing proved most efficacious in removing anaesthesia of the functional kind (Type I.). It had no influence on the recovery of the sensory lesions in the organic cases.

(b) *Symptomatic treatment.*—Attempts to relieve hyperæsthesia or the various subjective pains were made by the local application of pure glycerine on lint. This proved satisfactory in a few cases; it also has the merit of keeping the skin in good condition. As mentioned above, the counter-irritants sometimes have a soothing effect for a period. Aspirin and phenacetin were the only drugs given for the relief of pain. Doses either singly or combined, up to 80 grains in 24 hours, were said not to give much relief in severe cases. It was found that in the hyperæsthetic period (period of late reaction) the patient was more comfortable if the feet were raised on a pillow and exposed to the air or but lightly covered. Evaporating lotions also relieve the pain, but in two instances certainly set back ultimate recovery.

From so small a series of cases it would be idle to draw general conclusions. My account is indeed incomplete, as the most severe cases have not been followed to an end. I hope, however, that I may have made clear the type of case which may be expected to return to duty in a short period and to have indicated methods of treatment which are of some value.

No 2 St ti nary Hospital, Boulogne, Feb. 8th, 1915.

ON THE TREATMENT OF ACUTE EMPHYSEMATOUS GANGRENE DURING THE PRESENT WAR:

EXPERIENCES IN A CLEARING HOSPITAL.

By J. B. HAYCRAFT, M.B. EDIN.,
LIEUTENANT (TEMP.), R.A.M.C.

I THINK that it may be worth while briefly recording the experiences gained during the first six months of this war in a clearing hospital.

Emphysematous gangrene is described in surgical textbooks, and its bacteriology and treatment are fairly definitely laid down, and since the commencement of the war several articles have been written on the subject, both from the base hospitals and England. However, I am sure that the experience gained by those surgeons differs very materially from that of those who have to treat these cases close to the front, for often the conditions under which we have to work are of necessity not of the best, and also we see those cases which develop within a very short time of being wounded, and are, I am certain, more virulent than those cases of later onset which are seen farther down the line. Any one who has seen a number of these cases must be very forcibly struck by the terrible nature of the disease we have to cope with.

We know that the disease is caused by one or more anaerobic organisms of great virulence which thrive under certain conditions—e.g., absence of oxygen, the presence of aerobic organisms, and dead and sloughing tissues. Now, as Sir Anthony Bowlby and Dr. J. S. Rowlands have shown,¹ these organisms are present in a highly virulent state on the mud-stained clothing of soldiers who have been lying in trenches. Consequently it seems that in the prophylaxis of the disease it is rational to suppose that every wound, however slight, has been exposed to infection. The majority of these comparatively slight wounds progress quite well without showing any clinical signs of infection, but there is a small percentage which become infected, and if these are not very rapidly and energetically treated they spread with great speed and may lead to the loss of a limb or even life.

Classification.

It seems advisable to regard the disease as commencing as a localised infection which spreads very rapidly up and down the limb until a massive gangrene is produced, except in those cases of gross injury where the whole limb becomes gangrenous at once. As the mode of spread depends largely on the type of wound it is convenient to group the cases under these headings:—

Simple open wound, with sloughing and dead tissue at its base and discharging a dirty brown, foul-smelling fluid, with perhaps some bubbles of gas. There is generally some oedema round about and a brownish-yellow discolouration of the skin.

Simple closed wound, either produced by a rifle or shrapnel bullet. Entrance and exit wound sealed up. There is a good deal of swelling and the limb feels hot and tense, and is very tender and painful. On percussion a resonant note may be elicited over certain areas, or on palpation subcutaneous emphysema may be felt. On opening the wound foul-smelling fluid and gas escape.

Simple wound, vascular trauma.—The limb below the wound is at first livid and cold; there is

¹ THE LANCET, Nov. 28th, 1914, p. 1265.

generally some swelling, and the parts close to the wound are very tense. The circulation is abolished, but sensation is not as a rule lost. The whole limb soon becomes much more swollen, of a deep blue colour, changing to green or black; blebs form on the skin, and subcutaneous emphysema becomes marked and extends well above the gangrenous area, while the lower part of the limb becomes tense and resonant like a drum. The general condition of the patient is usually remarkably good for a time, and he does not show marked signs of septic absorption.

Lacerated wound.—Large wound of the soft parts, produced generally by a fragment of shell; there is generally a considerable quantity of muscle exposed and torn, and a good deal of dead and sloughing tissue turning black. There is foul discharge and gas spreading up the connective tissue planes of the limb and massive gangrene of a moist type rapidly ensues.

Severe wound.—Complicated by fracture, generally highly comminuted, of one of the long bones. If there is vascular trauma in addition there is added effusion of blood under great tension, which forms a large decomposing blood-clot or else the entire circulation may be suspended by thrombosis or pressure of a fragment of bone. If gangrene ensues in this variety it is usually extremely rapid, the whole limb becoming rapidly involved often in under 24 hours, with much formation of gas and a great deal of œdema.

Again, clinically there are, I think, various types of the disease depending to some extent on the nature of the wound, but there is a very considerable difference in the appearance of the tissues. The smell produced in different cases appreciably varies and also the amount of septic absorption, so that it would, I think, be very interesting to know if there were different organisms or a different combination of organisms present in the various kinds of cases. Clinically I would divide them into:—

Dry gassy type.—This form occurs when there is vascular trauma, either a solution of continuity of the vessel or more frequently thrombosis or interference in the circulation from outside pressure, such as a fragment of bone or the pressure of tight bandages or ill-fitting splints.

The limb at first becomes cold and livid in colour, is slightly swollen, and the patient complains of numbness and tingling sensations, though cutaneous sensation is not as a rule abolished. The distal pulse is obliterated or very feeble. Very rapidly the limb becomes more swollen, the colour changes to a deep blue, and finally a greenish black. The limb becomes tense and resonant like a drum, and subcutaneous crackling can be felt which extends high above the affected area; blebs form on the skin and discharge a foul-smelling brownish-coloured fluid.

The spread is extremely rapid, but the patient does not exhibit any marked signs of septic absorption until later. On section of the limb œdema is not a prominent feature though present to a certain extent in the subcutaneous tissues, and the muscles are a dark red colour, and except for a certain amount of hæmorrhage appear fairly healthy. The odour is quite distinct from the moist type.

Moist gassy type.—In this variety there is much more swelling due to œdema chiefly affecting the subcutaneous tissues, but also the muscles, which are swollen and rather pale in colour. There is considerable gas formation, both subcutaneous and

in the intermuscular connective tissue. The skin is not so discoloured as in the last variety, but is of a brownish colour, fading off at the spreading margin which appears somewhat raised and with darker patches here and there. On section a large quantity of foul-smelling fluid mixed with bubbles of gas escapes both from the subcutaneous tissues and from under the deep fascial planes. There is more marked evidence of septic absorption.

Digestive type.—Here the muscles are particularly affected; they become soft and friable and in places almost liquefied, with here and there pieces which are completely black and dead. It does not appear to spread so rapidly as the last two varieties, but leads to a great deal of septic absorption.

Septicæmic type.—This usually occurs in a severe wound. There is local evidence of infection, but as a rule there is no spread. Septic absorption is very marked from the beginning, the most prominent features being a sallow earthy complexion with a slight icteric tinge, persistent vomiting, and a soft rapid pulse, which very soon becomes imperceptible at the wrist, death often taking place within from 24 to 48 hours.

Prophylactic Treatment.

If one adopts the view that every wound has been subjected to infection, then the chances of successful prophylaxis depend on the following conditions:—

1. The sooner cases can be brought to clearing hospitals or other stations where thorough cleansing of wounds can be properly carried out, if necessary under an anæsthetic, the less risk will there be of infection taking a serious hold, and the more likelihood will there be of rendering the wounds as aseptic as possible.

2. Every wound, and this applies more particularly to wounds of the limbs, however slight, ought to be "dressed" every 12 hours at longest by a *medical officer* from the time of its infliction until the patient arrives at a base or other general hospital, and by dressing no mere inspection will suffice, but the whole limb must be thoroughly palpated and percussed in order to detect small areas of resonance or crepitation denoting gas formation. This particularly applies to those cases where there is only an entrance wound, as often such an area may be discovered at some considerable distance from the wound.

By systematically examining every case, however comfortable the patient may be, and however clean his bandages may appear, many cases will be discovered, and by immediate treatment can as a rule be prevented from spreading. To the surgeon at home this may seem an unnecessary point to raise where, of course, all wounds are dressed as frequently as necessary, but here, in times of emergency, when a very large number of wounded may suddenly arrive, it is no light task to carry it out properly, and one is often tempted to leave cases without dressing them which on the surface appear to be all right. However, I know by experience that the extra trouble involved is well repaid when one discovers these cases and is able to prevent further spread.

3. All bandages and splints must be very loosely applied; gauze should never be wound round a limb but laid over the wound in lengths. It is remarkable how quickly swelling may render them tight and further obstruct the circulation, a factor which greatly aids in the development of gangrene.

As regards the treatment of the wounds and the relative merits of the various antiseptics to be

used, I would like to say that, firstly, I do not believe that however powerful an antiseptic is used the wounds can be entirely freed from these anaerobic organisms, and this applies more particularly to the severer type of injury, such as compound fractures. I have formed this opinion from a series of cases which have been treated at this hospital by irrigation with carbolic acid 1 in 20 and finally painting over the wound with pure acid. A number of these cases were compound fractures of the humerus and femur, and they were most carefully "disinfected" in the above manner within 24 hours of infliction. They presented no clinical signs of infection, and unfortunately we have no means of bacteriological investigation. These cases were sent to a base hospital and were all labelled and treated with carbolic acid. I have since heard from Sir Anthony Bowlby that though in no case was a limb lost they all yielded cultures of anaerobic organisms. On the other hand, some of the cases in this series were obviously infected before being subjected to cleansing with carbolic. These cases did not do so well, and the infection did not seem to be checked, whereas when they were later treated with hydrogen peroxide they began to improve almost immediately. I think this is explainable, for the carbolic acid does not kill the organisms except perhaps on the surface, and here a slough is formed which, so to speak, seals up the wound and so produces a favourable site for their later growth. Therefore I would urge that these wounds be thoroughly opened up and cleaned out as soon as possible—those that are not obviously infected with carbolic acid or some other strong antiseptic, those that are with hydrogen peroxide.

Curative Treatment.

Adopting the previous classification the treatment of any given case will vary with the type and extent of the disease together with a consideration of the patient's general condition. I see in an article by Colonel C. B. Lawson and Lieutenant H. Beckwith Whitehouse in the *R.A.M.C. Journal* that they put great faith in the subcutaneous injection of hydrogen peroxide, and they claim that since this method has been introduced they have never had occasion to amputate a limb. That claim may be perfectly true for the cases which they have dealt with in a base hospital, but I maintain that there are cases which we get, often within 24 hours of being wounded, in which the injury to bone and soft parts is so severe, and the gangrene has spread so rapidly and to such an extent, that there can be no question of any other method of treatment than immediate amputation in order to save the life of the patient. Also in those cases where injury to main vessels dominates the picture and the limb below is cold, dead, and stinking, I can conceive of no conservative measures that will avail.

In my experience the spread of infection is not limited to the subcutaneous tissues even in the slighter wounds. One not infrequently sees gas oozing out from between muscles and also from the very depths of a wound, and I have seen most plainly the fascial sheath of a muscle raised up by small blebs of gas underneath it. How, then, is the subcutaneous injection of peroxide of hydrogen going to influence this? The treatment I have adopted is as follows, and I put it under three headings without being arbitrary, as each case must be judged on its own merits.

1. *Localised infection.*—The wound should be freely opened up with counter incisions for drainage

if necessary, all dead and sloughing tissues removed, and the cavity syringed freely with hydrogen peroxide, continuous immersion being practised when feasible.

2. *General infection.*—Those cases where there is no gross injury to bone or vessels, and where the general condition is good, should be treated by multiple and very free incisions opening up and communicating all the intermuscular planes; the openings should be kept open with drainage-tubes and frequently irrigated with hydrogen peroxide. Dressings should not be bulky and should be frequently changed. In these cases the subcutaneous injection of hydrogen peroxide in addition might be a help. If the condition spreads much or if signs of septic absorption appear then amputation ought to be performed at once.

3. *General infection.*—Where there is gross injury to vessels or bone then amputation should be immediately performed, except where continuous immersion is possible, particularly in the forearm.

Operation.

We have found that the use of champagne and rectal salines administered beforehand is of great value, especially in very bad cases whose general condition is bad. I have not seen a patient yet who with their aid was too bad to stand the operation, except the two in which the anatomical spread of the disease precluded it.

The operation should be performed as rapidly as possible, and the flaps, which should consist only of skin and subcutaneous tissue, should be longer than usual, the muscles and periosteum being detached up from the bone for some distance, so that in the event of sloughing of parts of the flaps secondary suture may be performed at a later date, doing away with the necessity of a secondary amputation. Where possible the longer flap should be made away from the inner side of the limb as the spread of infection is usually more marked and reaches a higher level along the course of the great veins, more particularly in the thigh. The presence of subcutaneous emphysema at the level of amputation does not seem to matter very much. This is very important, as otherwise in some cases one might have to perform disarticulation at the hip or shoulder which would entail much greater risk. In one case in which amputation was performed through dry emphysematous subcutaneous tissues I was able to have cultures taken by Mr. Rowlands, and they proved to be sterile. The whole stump should be well swabbed over with hydrogen peroxide and the flaps loosely stitched together, pieces of gauze soaked in hydrogen peroxide being placed between them and if necessary drainage-tubes introduced.

After-Treatment.

Apart from emphasising the value of champagne and salines, either intravenous with pituitary extract if urgent or per rectum, there is nothing to add. Dressings should be frequent and soaked in hydrogen peroxide and fomentations should be avoided.

If the flaps show signs of sloughing the stitches should be removed at once, the whole surface of the stump exposed and thoroughly irrigated with hydrogen peroxide at frequent intervals. This usually arrests further spread.

Prognosis.

Those cases which are slight and treated early and also those cases which can be treated by continuous immersions do extremely well. Of the more

advanced cases, in those without bone or vascular lesions a certain number can be saved by conservative measures, probably about 50 per cent. In those cases of the "dry gassy type" the prognosis after amputation in my experience has been very good both as regards the life of the patient and recurrence in the stump. It is in those cases of the "moist type," whether accompanied by severe bone lesion or not, that the prognosis is worst; the condition often recurs after high amputation, and though it may be eventually, though not always, checked by free opening up of the tissues the patient often reaches the top of the hill only to fall back again.

The immediate prognosis after amputation, even high up, seems to be very good, the patients stand the operation well and suffer very little from shock; indeed, one of the most striking as well as pathetic features of these cases is the remarkable fortitude which these poor fellows display. You will see them chatting and smoking cigarettes quite cheerfully less than an hour after having a leg or an arm amputated, and those cases which are on the point of death retain their mental activity almost right up to the end.

Summary of Cases.

I append the following list of cases which have come under my care in this hospital. They do not include the slighter cases nor those which have been treated by immersion, as I have, unfortunately, no record of them. We are under the disadvantage of being unable to follow up the cases to their termination, but we are able to keep them until infection has so far subsided as to permit of their safe removal, generally in from five to seven days after operation. Where recurrence has taken place it is usually from 24 to 48 hours after operation. In a few instances we have, where necessary, been able to keep the cases for a much longer period. I also fully recognise that up to the present the number of cases is too small to draw any conclusions which may not have to be modified in the future. The total number of cases is 27.

	No. of cases.	Cured.	Died.	Mortality per cent.
Treated by amputation { Arm 5 ... 5 ... 0 ...	5	5	0	23.81
(total 21) { Leg 16 ... 11 ... 5 ... }	16	11	5	
Treated by incision and drainage (total 4)	4	4	0	Nil.
No treatment (total 2)	2	0	2	100
Total	27	20	7	26.59

Of the cases treated by amputation which died, one case died three weeks later from secondary hæmorrhage from the external iliac artery in the original wound in the groin. The anaerobic infection had quite subsided. One case had an amputation performed through the lower third of the left thigh for a severe double compound fracture of the tibia and fibula, which showed signs of commencing infection. The stump became slightly infected but was doing well, when the other leg, which was covered with bomb wounds, including a perforating wound of the knee-joint, became badly infected. It was treated by multiple incisions and drainage, and the gangrene was of the digestive type. Nearly the whole of the anterior tibial muscles sloughed away, but the condition seemed to have ceased to spread. He showed, however, marked signs of septic absorption and suddenly collapsed and died. His age was 41 years. One case had both legs amputated, and recurrence ensued to a considerable extent in both stumps but was checked. He collapsed and died on the fourth day after the second

amputation. He was 40 years of age. Two cases died from recurrence, which could not be checked at all by incision and drainage of the stump. One of these was treated with lactic acid, which I have not had an opportunity of trying in other cases. One case which eventually recovered had an amputation performed below the knee too close to the gangrenous area. Recurrence rapidly ensued in the stump, and re-amputation was performed in the middle of the thigh. Recurrence again took place, but subsided on opening up the flaps and irrigating with hydrogen peroxide.

The two cases in which no treatment was attempted were: 1. A huge shell wound of the back of the thigh, with moist gangrene spreading up the buttock and abdominal wall as far as the umbilicus. His general condition was so bad that nothing could be attempted, and he died two hours after admission to hospital. 2. Gangrene of the left arm and left leg due to large shell wounds. He had been lost in a wood and left in the open for three days. He was moribund on admission and died three hours later.

Conclusions.

I think from the nature of the disease that most hope is to be expected from prophylactic rather than curative treatment. Unfortunately, it is impossible, for military reasons, to "get at" these wounds within an hour or two of their reception, but much may be done by vigorous treatment at the earliest possible moment, followed by a careful watch on each case.

Strong antiseptics should be used in wounds unless obviously infected, when hydrogen peroxide will prove most beneficial.

Conservative methods should be tried as much as possible, more especially where baths can be employed; if, however, they are not possible, as in bad infected compound fractures of the thigh, then amputation should be resorted to without delay.

I would like to take this opportunity of thanking Colonel Sir Anthony Bowlby for much kindly help and advice, and also our Commanding Officer, Major Symons, D.S.O., for the cordial assistance he has always rendered, enabling me to carry out the treatment suggested in these notes.

INCLUSION DERMoids OF THE PHARYNX.

By F. J. POYNTON, M.D. LOND., F.R.C.P. LOND.;

T. N. HIGGINS, F.R.C.S. ENG.;

AND

G. R. PIRIE, M.B. TORONTO, L.R.C.P. LOND., M.R.C.S. ENG.

THE occurrence of these tumours is very rare, but the clinical symptoms are of considerable interest on account of their peculiar characters and the tender age at which they usually occur. We have chosen for our case the name given first by Dr. W. Hale White,¹ it appealing to us as the most satisfactory.

The points of attachment of the recorded cases of these tumours—the pharyngeal wall in the region of the tonsillar pillars, the soft palate or the roof of the pharynx above the soft palate—coupled with their histological structure indicate clearly a relationship to the embryological activities which are manifested in this area. The infolding epiblast of the stomodæum fuses here with the anterior end of the foregut, and, as at all similar situations

¹ Hale White: Transactions of the Pathological Society of London 1881, p. 201.

throughout the body, we should expect malformations to occur now and then. Two other developmental features of the pharynx must also be borne in mind—namely, the development of the anterior lobe of the pituitary body by an epiblastic ingrowth from the roof of the pharynx, the remains of which persist normally in the pouch of Rathke, and secondly, the formation and closure of the branchial clefts. The symptoms produced in the following case may be taken as very characteristic of the class.

A female infant, aged 5 months, was brought to the hospital by her mother because for five weeks the mother had noticed some difficulty in swallowing milk and occasional attacks of coughing and dyspnoea. She had been curious enough to look into the child's mouth, and declared that she had seen a lump at the back of the throat which appeared at irregular times, and was then swallowed by the baby. The child appeared to be in perfect health, and on looking into the throat everything seemed natural, but on pushing the tongue-depressor well back and making the child "gag" a rounded, pinkish-white tumour suddenly appeared between the tongue and soft palate. It was evidently polypoid, and moved with such

rapidity that at one time it seemed to drop from the roof of the pharynx; at another to fly up from the depths of the throat. The swallowing efforts described by the mother were entirely accurate. Under anaesthesia the tumour was at first invisible, and was then found to be hidden by the soft palate, lying behind it in the nasopharynx. It was seized with the forceps and drawn forward, and was found to be attached to the left lateral pharyngeal wall between the anterior and

posterior pillars of the tonsils by a narrow pedicle. A stout catgut ligature was tied round the base and the stalk snapped off with scissors. There was no bleeding, and the base of attachment appeared to contain no blood-vessels of any size. Recovery was speedy and uneventful.

The specimen measured $1\frac{1}{2}$ inches in length, and was half an inch thick at its broadest part, and a quarter of an inch at its narrowest. The colour was a pale pinkish-white, and to the feel it was soft and smooth; it was covered sparsely with short, soft hair. On section with a knife it was rather tough, and at its centre there was a small cavity in which lying loosely was a small glistening, pearly-white plate of cartilage. Microscopy showed an external covering of thin skin with normal layers of compound epithelium. Under this was the subcutaneous stratum showing hair follicles and sebaceous glands. Deeper still was fibrous and fatty tissue, and in the centre cartilage. The accompanying illustration gives a clear idea of the appearance of a section under low magnification.

The diagnosis of such a case as this has only one difficulty—the possibility of overlooking the tumour in a superficial examination of the throat. If we are biased by an inclination to undervalue the statements of the mother, and owing to the rarity of the condition not aware of its existence, such an event would be possible, but otherwise there is no probability of error.

Eves,² who has collected 12 of these cases, recently published one very similar to the present case in a male child aged 14 months. This boy periodically vomited up the tumour, which then protruded from the mouth, and after it had been chewed for a while was again swallowed. As in our case, it was invisible until retching movements dislodged it from its usual position in the oesophagus. This tumour was attached by a long pedicle to the right side of the posterior pharyngeal wall behind the upper end of the posterior tonsillar pillar. Its structure was identical with ours except for the absence of cartilage. Removal was equally easy and bloodless. Hale White's case was a child 3 years old. The tumour was 2 inches long, "brighter red than the surrounding mucous membrane," and similar in structure to ours. It was apparently attached by a broad base to the soft palate behind the uvula. Aberham³ records a very remarkable case in which symptoms only arose just prior to removal of the tumour from a woman aged 22 years. The origin

in this case was from the region of the Eustachian tube. The surface was covered by well-formed hairs, and in the substance there was cartilage. Kidd's⁴ case was noteworthy on account of the complexity of the structure of the tumour. Measuring 8 by 6 inches, and springing from the palate, it protruded from the mouth of a newly born child, and consisted of skin,

A section across the tumour under low magnification. There are seen: (1) An outer covering of true skin with hair follicles and sebaceous glands; (2) retiform tissue; (3) a bar of cartilage lying obliquely to the right of the middle line; (4) a central canal probably due to the falling out of tissue during preparation.

subcutaneous tissue, with rudiments of bone, cartilage, and intestine. Arnold⁵ has described in an elaborate paper a number of cases in which similar mixed tumours were found attached to the pharyngeal region in still-born foetuses.

It appears to us that Kidd's case is the only recorded instance in which the tumour contained structures representative of all three layers of the embryo, and thus meriting the title of "teratoma," which has been given to these growths by some writers. It is for this reason we incline to Hale White's original explanation. Hale White considered that the varying nature and attachment of these tumours pointed to elements gone astray in the fusion of the foregut with the pharynx, and compared them to the four tufts of hair which are normal in such rodents as the rabbit.

ON BACILLUS PROTEUS INFECTION,

MORE ESPECIALLY IN RELATION TO A CASE OF
PROTEUS SEPTICÆMIA ASSOCIATED WITH
FEMORAL THROMBOSIS, PULMONARY
EMBOLISM, AND RECOVERY.

BY CUTHBERT S. WALLACE, F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL, LONDON;

AND

LEONARD S. DUDGEON, F.R.C.P. LOND.,
BACTERIOLOGIST TO ST. THOMAS'S HOSPITAL.

IN this communication we wish to record a case of considerable interest both clinically and bacteriologically, and then briefly to refer to other infections caused by proteus bacteria.

The Clinical History.

The patient, a male aged 60, suffered from complete retention from an enlarged prostate. The urine was clear and acid. A three-lobed tumour surrounded by some circumferential fibres was removed by the suprapubic route. A distinct shelf of mucous membrane was left between the bladder and the cavity from which the obstructing adenomata were removed. The course was uneventful, and the general condition of the patient was excellent, although at the end of five weeks no urine was passed by the natural route. The suprapubic sinus was enlarged, a finger introduced into the bladder, and a steel sound was passed along the urethra. It was found that the mucous membrane had healed completely over the entrance of the urethra into the bladder. The sound was pushed through and the edges of the obstructing membrane were divided radially with scissors. The patient became gravely ill, with a sustained high temperature, and very rapidly showed considerable loss of flesh. The high degree of pyrexia was associated with definite rigors. Thirteen days from the onset of this acute illness thrombosis of the deep veins of the right leg was detected, together with great œdema of the surrounding tissues. On several occasions it seemed as if supuration had supervened, owing to several very painful areas in the boggy tissue of the enormously swollen thigh. A firm, tender cord along the course of the right femoral vein could be detected for several inches. Three weeks from the onset of the thrombosis the patient developed a severe and sudden illness affecting the cardio-respiratory system, probably due to a pulmonary embolism. It is doubtful if a patient was ever in a graver condition, but once the limit of the acute illness was reached he began to improve distinctly, and the progress towards recovery was as rapid as the downward course had been. The pyrexia decreased in severity and the swelling in the leg began to diminish, so that in three and a half months from the onset he was able to return to his house in the country in a comparatively good state of health and without any visible abnormality in the legs. The act of micturition was completed in a normal manner in every respect. The pyrexia during the height of the illness varied between 100° and 105° F., while the pulse was generally rapid and often very irregular. He never had a rash and no physical sign beyond those already referred to except an attack of tonsillitis, from which we were unable to cultivate the bacillus proteus.

Bacteriological Examination.

Blood.—A good supply of blood was obtained from a vein and various media were inoculated, including a 2 per cent. solution of bile salts in distilled water. An abundant growth of a bacillus was obtained in this medium within 24 hours, while at the end of 48 hours the other media gave a similar result. This organism, when fully investigated, was found to be identical with the bacillus cultivated from the urine.

Urine.—There was a deposit of pus, and bacilli were numerous. A sample of the urine plated direct on bile-salt lactose neutral-red agar gave a pure culture of the bacillus about to be described in detail.

Cultural Characteristics.

Neutral-red bile-salt lactose agar.—A growth of the organism on this medium changed the colour to a yellowish brown and the individual colonies were of a similar appearance.

Gelatine.—Rapid liquefaction occurred.

Litmus milk.—This medium was acidified, then decolourised, and the clot which formed was rapidly peptonised.

Neutral red broth.—Marked green fluorescence was produced and the medium was altered to a canary-yellow colour.

Peptone water.—No indol formation occurred at the end of ten days.

Blood serum.—Liquefied within a few days at 37° C.

Litmus dextrose.—Acidified, decolourised, and abundant formation of gas.

Litmus cane sugar.—Acidified, decolourised, and slight production of gas.

Dulcitate and maltose were acidified and decolourised, but no gas formation occurred, while sorbite, lactose, and mannite were unaffected.

Agglutination Reaction.

A 24-hour culture of the bacillus was obtained on agar, emulsified in saline, and tested with stock antiproteus serum. The serum was prepared by immunising rabbits with filtered and boiled aggressive exudates obtained from proteus infections, as detailed in the Croonian lectures of 1912.¹ Cultures of this bacillus isolated from the urine and blood and tested with this serum in dilutions of 1 in 10, 1 in 50, 1 in 100, and 1 in 200 gave a strong agglutination reaction both by the microscopical method and the sedimentation test. Control normal serum exerted no clumping action when treated with this bacillus in similar dilutions, while atypical members of the proteus group agglutinated to a limited degree in the presence of this serum.

Pathogenicity.

This bacillus was found to be pathogenic in guinea-pigs when injected intraperitoneally. The animals died within 24 hours from acute diffuse peritonitis. The abdominal viscera were soft and friable and mostly covered with an inflammatory exudate. In each instance a pure culture was obtained from the peritoneal exudate of a bacillus with similar cultural characters.

As regards the pathogenicity of this bacillus for guinea-pigs the results were not constant, as some animals recovered after a severe illness which cannot be regarded as an exception with bacteria of

¹ Dudgeon, L. S.: The Pathology of Immunity—more especially with regard to the Problem of Aggressins, the Croonian lectures, THE LANCET, June 15th, 22nd, and 29th, and July 6th, 1912.

this group. When injected subcutaneously a lesion of minor importance may be excited, unless a heavy dose has been injected, when a fatal result may ensue.

Action of the Proteus Bacillus on Urine.

Samples of normal human urine were sterilised by exposure to a temperature of 60°C. for four hours. Experiments were made by inoculating tubes of the sterile urine with this strain of proteus and incubating one batch at 37°C. with control tubes uninoculated, and contrasting the results with similar tubes of sterile urine also inoculated with proteus, but left at room temperature. The only tubes which were altered at the end of 24 hours were those which had been inoculated and incubated at 37°C. These were very turbid, showed a heavy deposit of triple phosphates and carbonates, and omitted a foul ammoniacal odour. It was found at the end of five days that the inoculated tubes of urine which had been left at room temperature were sterile, but when transferred to the warm incubator the urine was decomposed in the manner indicated above. These results occurred both aerobically and anaerobically.

Horton Smith² published some observations made by him on proteus infection of sterilised urine, and showed that the strain he was investigating decomposed the urine, setting free ammonia and precipitating triple phosphates.

The absence of decomposition of the urine at room temperature is of interest, but the rapid activity of the proteus bacillus when such samples of urine are transferred to a temperature of 37°C. is emphasised, and such results agree with certain experiments given by McWeeney in a paper which will be referred to later. Here he states that slices of potatoes inoculated with proteus bacilli and kept at 10–12°C. were found not to be toxic.

Treatment.

When the patient was first seen with a view to special treatment to be directed against the bacterial infection he was so desperately ill that urgent remedies had to be adopted before complete investigation of the case could be completed. As the infection had originated in the urinary tract and a bacillus had been cultivated from the blood stream it was supposed that we were dealing with a case of septicæmia due to the bacillus coli, a supposition which would be correct in the vast majority of similar cases. Anticoli serum was administered (50 c.c.), followed in 12 hours with 25 c.c., but without any material effect on the clinical condition or on the pyrexia. It was discovered by this time that the infecting organism belonged to the proteus group; an injection of proteus vaccine was administered, and as soon as possible the patient received the autogenous vaccine in gradually increasing doses of 15 to 30 million, while as the general condition improved the dose was increased until he finally received 500 million bacilli at each injection.

The inoculations from the first produced a distinct beneficial effect, although some rise of temperature occurred, while later large numbers of bacilli were administered without causing more than a slight degree of pyrexia. The improvement induced in the tissues affected by the thrombosed veins was remarkable, more especially when the acute stage of the infective process had diminished

in intensity. In our opinion such rapid recovery from so grave an infection could have been induced only by means of a specific bacterial product.

Acute and Chronic Infections Caused by Proteus Bacteria.

For some years we have investigated various infections due to bacilli of this group,³ although the case under discussion is unique in our experience. The commonest infections caused by proteus bacilli undoubtedly are pyuria due to cystitis, non-empysematous gangrene of infected wounds, infected sinuses, and chronic localised infective processes of various kinds. Two of the most widespread suppurative inflammations of the skin which we have ever seen were due to the proteus bacillus. In both instances these cases had been diagnosed clinically and treated as staphylococcal infections, but all to no purpose. Infection of wounds by the proteus group may be of a simple or suppurative character, and a non-empysematous but spreading gangrene may be induced by this organism as already referred to. One of us (L. S. D.) met with a case of this kind in which the whole abdominal wound became gangrenous from an infection originating in an undiagnosed proteus pyuria. Undoubtedly the commonest infections caused by members of this group are confined to the urinary tract. It is the proteus group which produce the peculiarly offensive odour of the urine so well known in some forms of cystitis and so fully represented in the badly flushed urinals by no means uncommonly met with even at the present day. The saprophytic life of the proteus group is so fully recognised that the pathogenicity may be and often is overlooked. In fact, it is unintelligible to those who see proteus infections so often that textbooks on bacteriology should give so little information on the subject.

Proteus infections as a rule are mild, occasionally severe, but the severity of the infection met with in the case under discussion is unique in our experience. Hicks⁴ recorded a fatal case of septicæmia from which he recovered a proteus bacillus from the blood during life and from the tissue at the necropsy. McWeeney,⁵ in an interesting paper on meat poisoning already referred to, classifies such infections into three groups, one of which he calls "the group of putrefactive aerobes (proteus)." He, however, lays too much stress on the saprophytic existence of this group of bacteria as shown by the following sentence: "We have had to deal with a group of cases referred with more or less probability to the action of organisms that lead a saprophytic existence in dead matter, and do not, as a rule, produce specific infective disease in living men or animals." In this paper reference is made to infection of meat food with proteus bacilli and to a most interesting outbreak of food poisoning recorded by Dieudonné in which 180 Prussian soldiers were infected by a potato salad found to be saturated with this organism.

A case of meningitis due to a proteus bacillus was recorded by Ross,⁶ and in this instance the organism in question was cultivated from the cerebro-spinal fluid during life. The proteus bacillus

² Smith, P. Horton: On Bacillus Proteus Urinae: A New Variety of the Proteus Group, discovered in the Urine of a Patient Suffering from Cystitis, Journal of Pathology and Bacteriology, 1897, vol. iv.

³ The cultural characters of the organism described here are regarded by us as typical, but large numbers of strains atypical culturally and by agglutination tests are commonly met with.

⁴ Hicks, J. A. B.: A Bacillus of an Unusual Kind Isolated from a Case of Septicæmia, THE LANCET, May 31st, 1913, p. 1526.

⁶ Ross, E. Athole: A Case of Meningitis, THE LANCET, Nov. 9th, 1912, p. 1292.

isolated by Ross in this case was not the typical organism according to the cultural characters given in his paper, but it had many points in common with bacteria of this family. It has been claimed that infantile diarrhoea is due to bacilli of this group, and certain observers consider that infectious jaundice is excited by a special proteus bacillus. It should be fully recognised by clinicians that proteus bacteria are capable of exciting various infections in the human subject, mostly chronic or mild in character, but sometimes severe. The fact that this organism so often exists in the human body without exciting a severe illness has led to the belief that it is incapable of exerting a severe pathogenic effect.

A SIMPLE METHOD OF TREATING GUNSHOT WOUNDS OF THE HUMERUS.

(SUPPURATING COMPOUND COMMINUTED FRACTURE.)

BY PAUL BERNARD ROTH, M.B., CH.B. ABERD.,
F.R.C.S. ENG.,

SURGEON, KENSINGTON GENERAL HOSPITAL; SENIOR ORTHOPÆDIC
CLINICAL ASSISTANT, LONDON HOSPITAL; CAPTAIN R.A.M.C. (S.R.)
I.C. SURGICAL DIVISION, CAMBRIDGE HOSPITAL, ALDERSHOT.

THIS method, which consists of slinging the wrist to the neck, has been in use here since the beginning of the war with complete success. On arrival at the hospital the patient is stripped to the waist, seated on a chair, and all dressings and splints removed. He is then instructed to take hold of the hand of the injured arm with his other hand, and slowly to bend the elbow, raising the hand as near to his neck as possible, with the elbow hanging down. The hand is then fixed there in the sling described by H. O. Thomas, of Liverpool, as the "gauge halter," but which may be conveniently called the "Thomas sling."

To apply this sling a 4-inch flannel bandage 3 yards long is knotted fairly closely round the neck, with the two ends hanging down equally. Where these two ends come opposite the upper border of the wrist, the elbow being flexed in the manner described, another knot is made, and one end passed in front of the wrist and one behind it. The wrist is now pushed snugly up against this knot, and the end which passed in front is turned up behind, and the end which passed down behind is turned up in front, and the two tied above the wrist again in a third knot. (Fig. 1.) Some wool is introduced between the bandage and the wrist to prevent chafing.

Antiseptic dressings are then applied to the wound and are kept in position around the arm with a triangular bandage. The patient is put to bed and kept propped up with pillows in a sitting position so as to allow the elbow to hang down. As soon as he feels fit enough he is encouraged to get up and sit about the ward, and even walk about in the garden, the elbow hanging down the whole while.

Though such injuries often appear hopelessly septic, with pus pouring out of the wounds of entry and exit, and with considerable tumefaction, a few days of this treatment produce a wonderful change for the better in them, and beyond enlarging the wounds and inserting a tube if the drainage is not sufficient, no further treatment besides frequently changing the dressings is required. On no account must the comminuted portions of bone be removed at this stage; most of them will heal in and help in

reforming the shaft. Any fragments which necrose can be removed months later without risk then of taking away useful bone. The patient's wrist is kept in this sling night and day for five or six weeks until bony union has taken place. When the patient can voluntarily raise his hand in the sling and touch his forehead it is safe to let him come out of it.

FIG. 1.

The Thomas sling in position.

If a radiogram is wanted during this period it is taken in the sling, the plate being placed between the body and the arm. When required, fresh dressings can be applied without ever taking the limb out. The patient simply leans over in the sitting position so as to let the elbow hang clear of his side, when the dressings can be changed without disturbing the bones in any way—wherever the wounds may be situated—the whole process occupying less than a couple of minutes.

The weight of the elbow acts as a constant extending force, producing good alignment, and as there is no movement of the parts, even when the dressings are changed, the patient suffers the minimum of discomfort and is spared the pain of daily dressing which seems inseparable from other methods of treatment. By the use of this sling bony union with complete range of extension and flexion is assured. If Medical Officers with the Expeditionary Force were to adopt it, much time would be saved, much suffering avoided, and many useful limbs obtained.

The following is an illustrative case:—

Lance-Corporal, 4th Royal Fusiliers, received on Sept. 19th, 1914, on the Aisne, a shell wound of the left upper arm. Oct. 2nd: Arrived at Cambridge Hospital, Aldershot, in great pain. The arm was much swollen, pus welling out from the wounds. Thomas's sling applied the same night.

day. Sent to Auxiliary Hospital, where he remained 14 weeks, with a small sinus discharging on the outer side of the arm the whole time. Feb. 12th, 1915: Returned to Cambridge Hospital. Can voluntarily flex elbow completely, and extend to 150°; pronation and supination perfect. Radiogram (Fig. 3) shows stout bony union with good alignment. Comminuted portions of bone have all healed in, except for

FIG. 2.

Radiogram showing comminuted fracture of humerus.

FIG. 3.

Radiogram showing stout bony union with good alignment.

Oct. 3rd: A radiogram (Fig. 2) taken by Dr. Hernaman-Johnson, radiologist to the hospital, showed severe comminution, with the shaft practically obliterated for an inch. Oct. 5th: Drainage-tube inserted. Oct. 12th: Arm immensely improved; no pain whatever. Nov. 6th: Bony union; given permission to take wrist out of sling a little every

a few minute necrosed fragments lying in an abscess cavity. Feb. 14th: Necrosed fragments removed with spoon. Feb. 19th: Sinus closing, no discharge. Left again for Auxiliary Hospital.

My thanks are due to the Commanding Officer for kind permission to publish this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Clinical Cases.

A MEETING of this section was held on March 12th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. J. PORTER PARKINSON showed a case of Tumour of the Neck with Obstruction of the Superior Vena Cava. The patient, a woman aged 50, had had lumps in the neck since the age of 10; these increased about the age of 20, but diminished under the application of iodine. She married when aged 30, and had had three children and no miscarriages. At the age of 34 the neck suddenly became stiff and she had severe pains; the latter had since gone, but the stiffness had increased. Four or five years ago she noticed enlarged veins on the chest, and these had steadily increased in size. She had been getting somewhat thinner for the last eight years. On admission to hospital she was a somewhat thin woman, weighing 7st. 6lb. The head was held rigidly, somewhat bent forward, and not the slightest rotation could be produced. The muscles of the back of the neck were large and exceedingly hard, almost as if converted into bone. On each side of the neck, under the sternomastoids, was a somewhat irregular mass which moved

on palpation; and on swallowing its consistence varied from an indefinite fluctuation in some parts to a cartilaginous hardness in others. It was not adherent to the skin or surrounding parts. The isthmus of the thyroid could be felt, but was not enlarged to any great extent. The right carotid artery was displaced backwards. There was enormous dilatation of the veins of the chest and abdomen, the direction of the blood-flow being downwards. Nothing abnormal could be made out in the chest or abdomen. The urine was normal. The temperature varied between 98° and 99·4° F. Skiagrams showed no change in the vertebral column, no ossification of the muscles of the neck, and nothing abnormal in the chest. After a month's treatment of the muscles of the neck by potassium iodide ionisation some slight movements of the neck were possible, but on the whole the condition was unchanged. The Wassermann reaction was negative. The case was brought for suggestions as to diagnosis: first, as to the nature of the tumours of the neck and the condition of the muscles; and secondly, the cause of the interference with the superior vena cava. The neck tumours were, Dr. Parkinson suggested, enlargements of the lateral lobes of the thyroid of the nature of a cystic adenoma partially calcified.

Dr. F. PARKES WEBER showed a case of Non-syphilitic Arteritis Obliterans ("Thrombo-angiitis" of Leo Buerger), with Gangrene of Toes. The patient, aged 25, a Jew, had come from Russia to London nine years ago. He was delicate-looking and thin, having, as he said, lost about 28 lb. in weight during the last two years. He denied having had any venereal disease. Seven years ago he first had trouble in his left foot and a doctor removed the nail of

the big toe, which he thought was "ingrowing." Gangrene of the big toe followed, and ultimately, about 12 weeks later, the whole of his big toe had to be removed. The wound healed up and for a long time the patient had no further symptoms in his feet. In March, 1913, however, he got his feet thoroughly chilled and then warmed them in front of a fire. Thereupon, though the left foot did not suffer, the distal portion of the right foot became painful and red and afterwards purple. The pain was so severe that he could not sleep. The nail of the right great toe, which looked quite black, had to be removed, and the great toe itself became permanently contracted. After the patient had been laid up several weeks the pain gradually diminished and then disappeared, but the cyanotic colouring of the foot persisted, though varying in degree from time to time. About five weeks ago the left foot assumed the same cyanotic appearance as the right foot, but he suffered no pain in either foot, though sometimes there was a sensation of "pins and needles." For the last two years there had been a condition of "intermittent claudication" in both legs. He used to smoke about 20 cigarettes daily. He said that he had never been subject to chilblains. The distal portions of both feet were cyanotic, the right more so than the left; the colour varied from time to time, especially according to position. Thus, when the feet were raised up they became paler, and when they were allowed to hang down they became more cyanosed. Both feet felt cold. Pulsation could not be detected in either right or left dorsalis pedis artery, or in any of the arteries of the feet. There was no air pulsation in both femoral arteries at the groin. The great toe of the right foot was permanently contracted in a flexed position. There was a certain amount of "glossy" trophic disturbance in the skin of the toes of both feet and a scabby scar of a recently healed ulcer on the right heel, where intermittent pressure occurred in walking. The patient thought that his legs had wasted during the last two years, but only in proportion to the general wasting of his whole body. He had well-marked signs of valvular disease of the heart with hypertrophy of the left ventricle, probably of rheumatic origin, though there was no history of rheumatic fever. The physical signs were those of aortic reflux, and there was also a musical systolic murmur, best heard at the apex. The brachial systolic blood pressure equalled 160 mm. Hg. The blood serum gave a negative Wassermann reaction or syphilis. Dr. Weber regarded the case as one of non-phlogistic arteritis obliterans (the "thrombo-angiitis obliterans" of Leo Buerger), occurring, as it most frequently does, in a young adult male of Jewish stock from Eastern Europe. The exciting cause of the onset of the symptoms in the patient's right foot was a kind of "frost-bite," but the patient had already previously had disease in the other foot without "frost-bite" of any kind connected with it. In this association it was interesting to note that the condition of the foot after some cases of so-called "trench frost-bite" (French, *mal des tranohées*) observed amongst the soldiers in the present war resembled the state of the foot in cases like the present one. The connexion of other kinds of auma with cases like the present one might also sometimes be confusing. Thus, in a patient recently at the hospital there was a history that a cab went over his foot. The patient was a Jew, aged 37, with a very painful condition of the left foot, which kept him awake at night. The distal portion of the foot was red or purple, and there were black patches of superficial dry gangrene over the great toe and the heel. Pulsation was absent in the dorsal artery of the left foot, but was present in the dorsal artery of the right (sound) foot. The left foot had certainly been run over, but the patient had complained of pains long previously, and slight atrophy of the calf muscles of the left leg had been recorded three months before the accident, when the patient was at a health resort for treatment.

Dr. WEBER also showed a case of Sclerodactylia of Feet associated with Arteritis Obliterans and Gangrene of Toes, and a case of Acromegaly; also skiagrams of a case of the Morvan Type of Syringomyelia. With regard to the last mentioned, he said that in 1883 Morvan, a French doctor, working in Brittany, described cases of a trophic disorder of the extremities associated with the formation of painless ulcers and areas of analgesia. Though Zambaco Pasha (Constantinople) tried to prove that Morvan's cases were bad examples of attenuated leprosy (occurring in

Europe), Charcot, Marinesco, Jeanselme, and others succeeded in proving that most of them were due to syringomyelia, and Charcot termed the so-called "Morvan's disease" (or rather syndrome or symptom-complex) the "Morvan type of syringomyelia." The present case was that of a man, aged 45, who for the last 15 months had suffered from trophic disturbances in the hands characterised by the occasional formation of scabs, which gradually peeled off. There was no condition of actual "cheiromegalia," as occurred in some cases of syringomyelia, nor was the process of scab formation on the fingers associated with actual suppuration. The patient's toes were somewhat "clubbed," and the local thickenings of the skin over the toe-tips apparently corresponded to the scabs on the finger-tips. There were areas of analgesia on the forearms and legs. The ulnar nerves at the elbows felt perhaps somewhat thicker than in most persons, but there was no real evidence of anæsthetic leprosy, and the patient said he had not been out of Europe during the last 16 years. The Roentgen skiagrams of the hands and feet confirmed the view that trophic changes in these parts in cases of syringomyelia were practically confined to the soft parts, leaving the bones unaffected. There was no kyphosis or deformity of the back. There was no acromegaly-like change in the patient's face, such as had been rarely met with in cases of syringomyelia. Though the scab formation in the fingers was painless, the patient did suffer from subjective pains (some of Morvan's patients complained of "neuralgic pains"), notably what he called "sticking pains" in the fingers in cold weather. The pupils reacted to light and accommodation. The knee-jerks were somewhat exaggerated. The plantar reflexes were active and of the normal (flexor) type. The blood serum gave a negative Wassermann reaction. There was no muscular wasting.

Dr. WEBER then read a short paper on a case of Splenomegaly with the clinical picture of Banti's disease.

SECTION OF OPHTHALMOLOGY.

The Montessori System and its Use for Children with Defective Vision.—Education of Children with Defective Vision.—Exhibition of Clinical Cases.

A MEETING of this section was held on March 3rd, Mr. J. B. LAWFOORD, Vice-President, being in the chair.

Mr. LESLIE J. PATON read a paper entitled "The Montessori System and its Use for Children with Defective Vision." He said his attention was called to the value of this system of education in the case of children with defective sight by having a patient, aged 2½ years, in whom severe ophthalmia neonatorum had caused blindness in the left eye and very defective vision in its fellow. He was greatly impressed a year later by the boy's general intelligence and by the fact that he knew his letters and could count small numbers. The parents ascribed this improvement to six months' training which he had received at a Montessori school. The method was most applicable to children between 3 and 6 years of age, the most important period of sensory education. There were several of these schools in the country, but the difficulty was to find the right conductor. It was difficult to resist the temptation to interfere with the child, but the reward came in the child's intense satisfaction when he had succeeded unaided. If the child were really interested in his task no outside influence would prevent his continuance at it. Even in normal children most of the exercises were done blindfolded, so as to exercise the tactile muscular and stereognostic senses. By this system vision played but a small part in learning to write: the art was acquired almost as a by-product during the training of the tactile muscular sense. Mr. Paton described, aided by the actual models, the kind of training given, which included the discrimination of various sounds and rhythm. The method enabled children to perform by the assistance of these senses many complex acts accurately. A difficulty with English children, however, was the fact that English was perhaps the least phonetic of European languages, while the Italian was almost purely phonetic. It left the child to develop its inherent capacities, in opposition to the usual method of inculcating from outside truths in the form of dogma. The children seemed to be unconscious that they were doing more than playing at a most absorbing game, yet they were undergoing self-discipline and a social recognition of duties to others.

Mr. N. BISHOP HARMAN read a paper on the cognate subject of the Education of Children with Defective Vision. The claims of the Montessori system were compared with the scheme of myope classes which had been working in this country and America for seven years. In Italy the Montessori system had one great advantage over the current modes of education, in that it allowed for the personality of the child, and it had proved of great value for mental defectives. But the spirit of England was against anything in the nature of drill-sergeant education, personality having always been fully recognised; moreover, in its technical methods the Montessori system had nothing new to offer, and it had been claimed that a substitution of feeling for sight was a reversion to a lower order of things. If the claim were substantiated that by the Montessori system a child learned to read two years earlier than by the ordinary methods, it effectively condemned the system for children with defective vision; it placed the child too early into the unreal world of books, and there was an absence of childish questioning for information. The myope class had a natural origin, numbers of short-sighted children had to be dealt with. The scheme resolved itself into three parts: (1) Oral teaching with normal children; (2) literary work in the special class where all the work was done on blackboards; and (3) handicraft work, which had both utilitarian and "expressional" value, and to this work were attached the practice of history, arithmetic, geography, and so on. Despite the regulation forbidding work necessitating stooping and the use of rules and scales, the handicraft work had been highly developed. It was working as a full scheme in elementary schools for children aged from 7 to 14 years, and was also used, with modifications, in the teaching of children in well-known public schools with equal success.

The papers were discussed by Mr. CHARLES WRAY and Dr. G. E. SHUTTLEWORTH, and Mr. PATON and Mr. BISHOP HARMAN replied.

The following clinical cases were shown:—

Mr. A. C. HUDSON: Two cases of Couching of the Lens.

Mr. STEPHEN MAYOU: Glaucoma in a boy aged 17 years.

Mr. G. W. ROLL: (1) Bullet Wound of Orbit; and (2) Proptosis.

Mr. RAYNER BATTEN: Vascular Keratitis of Upper Third of Cornea, with Terminal Perivascular Deposits.

Mr. WRAY: Conical Cornea.

ROUEN MEDICAL SOCIETY (ROYAL ARMY MEDICAL CORPS).

Typhoid Fever

A MEETING of this society was held at No. 11 Stationary Hospital, Rouen, on Feb. 13th, Colonel B. M. SKINNER being in the chair.

The following committee was appointed to conduct the affairs of the society, the A.D.M.S., Rouen, consulting physicians and surgeons, and honorary general secretary to be *ex-officio* members of the committee: Lieutenant-Colonel C. B. Lawson, Major A. J. Hull, Major Adye-Curran, Lieutenant Struthers, and Lieutenant Harold Wiltshire. Lieutenant Beckwith Whitehouse was elected to undertake the duties of honorary secretary and treasurer.

Colonel SKINNER announced that a large consignment of medical and surgical books had been received from Messrs. W. B. Saunders Company for the use of members of the society, and these had been placed in a room at the Hotel de la Poste, kindly placed at the disposal of members by Colonel Sir Berkeley Moynihan.

Colonel Sir BERTRAND DAWSON, in opening a discussion on Typhoid Fever, said that he proposed to treat the subject under the following headings: (1) Early diagnosis; (2) atypical cases; (3) the results of inoculation; and (4) the coexistence of typhoid and paratyphoid. The most important points in the early recognition of the disease are headache, fever, a low pulse-rate, and cough. If typhoid is ripe and a patient presents himself with a temperature of 103° F., pulse 90-100, and headache cultures should be made at once and a dose of vaccine administered. In about 30 per cent. of cases epistaxis occurs as well, and must be noted in relation with the above symptoms. Mistakes are most likely to occur in relation with meningitis, influenza,

and measles. Measles is usually quite evident by the fourth day. The slowness of the pulse in relation to temperature is most striking and helpful. It is not uncommon to find fever of 102° and 103° associated with a pulse well under 100. Furthermore, the pulse-rate may frequently be regarded as of prophetic value. Thus, a pulse consistently below 100 indicates spontaneous recovery. On the other hand, a rising and high pulse-rate means a severe infection. Frequently the rate will increase to 105 or 110 long before other symptoms arise. It is advisable to chart the pulse readings as well as the temperature for reference. If the pulse line remains below the temperature all is well; if it mingles with the latter complications may be expected; if, on the other hand, the tracing wanders above the temperature line danger is foreboded. The speaker illustrated these remarks by a series of charts. As regards the diagnosis between typhoid and meningitis and influenza some difficulty may arise, owing to the fact that both diseases have a slow pulse in relation to temperature. In meningitis pain and stiffness of the neck and the initial vomiting are important diagnostic points. The banished abdominal reflex does not help much, as it is sometimes common to both diseases. Kernig's sign and absence of knee-jerks have also been noted in typhoid. Lumbar puncture may be performed in doubtful cases, but only when other diagnostic signs have failed. Influenza more frequently gives rise to mistakes in diagnosis. In both typhoid and influenza headache is present, and in both a sore throat may exist. Influenza, however, always presents physical signs by the fourth day of the disease. The most important of these is fine bronchitic signs and blocking of the lung bases. This may occur in typhoid also, but the clinical picture is totally different. The influenza patient under these conditions is restless and excitable, whereas the typhoid individual is somnolent and apathetic. Swabs may be taken from the throat, but it must be remembered that the influenza bacillus is easily missed. As regards a blood count, typhoid is undoubtedly one of the fevers that give a leucopenia; but with influenza it is not uncommon also. In discussing paratyphoid Sir Bertrand Dawson observed that paratyphoid A is hardly known in England, although of common occurrence in India. Paratyphoid B, on the other hand, occurs not infrequently and he thought that many cases are probably being missed at the present time and not reaching the base hospitals. Clinically, the disease is often indistinguishable from typhoid, exhibiting the characteristic splenic enlargement, spots, bronchitis, &c. The cases recover more quickly, however, and relapses are less frequent. He did not remember a single case in which perforation had occurred. As regards the temperature, the fever is remittent from the first and subsides about the sixteenth day. Considerable difficulty arises in the diagnosis of the slight cases. The patients are usually seen at too late a stage to get a blood culture, and the temperature only lasts for three or four days. In a series of 6 cases of slight fever recently investigated 2 proved to be paratyphoid. With regard to the question of antityphoid prophylactic inoculation, he has investigated a series of 27 cases of paratyphoid B. Of these 21 had been inoculated. He suggested that if the incidence of paratyphoid increases the prophylactic vaccine should be a mixed one and include strains of paratyphoid B. The disease is communicated probably by carriers and direct contact. Discussing the relation of prophylactic inoculation and true typhoid, Sir Bertrand Dawson noted that in recent severe cases 14 only had been previously inoculated and 47 untreated. Of 37 mild cases, 28 had received vaccine previously and 9 had not. The proportion in each is therefore about 3 to 1. No death had occurred in the inoculated cases, although there had been two narrow escapes. Referring to the Widal test, the speaker observed that it is the disadvantage of not being available during the first week. Also it is always present after inoculation, and although the dilution increases during the progress of the disease the information given is necessarily late. Furthermore, the test is eccentric. He cited various instances in support of this fact. In one case the blood was positive to typhoid, but the Widal was negative throughout. In another case the test was positive one day, negative the next, and positive again the next. In yet another patient the Widal was negative two days before death and positive in blood taken post mortem. People are apt, therefore, to put too much reliance upon the

test. From a clinician's point of view nothing comes up to a blood count. With regard to blood cultures it is curious how in some cases they are always negative. Does this mean that the bacilli are absent from the blood or present in very minute numbers or is the culture medium not correct? It is known that the B organisms are present in plenty in the spleen, and the speaker asked if it was possible to obtain the blood for culture from such an organ or perhaps the liver. Puncture of the latter organ may easily be performed between the eighth and ninth ribs, and if a medium-sized needle is employed sufficient blood withdrawn for culture purposes. Examination of the stools becomes of increasing importance owing to the failure of the Widal test due to inoculation. With regard to therapeutics, most interest centres round specific treatment. It is very difficult to maintain an open mind on this matter, and to designate between *post hoc* and *propter hoc*. On the one hand is the man who sees very little good derived from vaccines, and on the other is the man who lauds them to the skies. Whilst it is easy to estimate correctly the value of vaccines in the chronic lesions, it is difficult to judge success in the acute conditions. The only criteria upon which to base deductions are (1) statistics, and (2) clinical data. With regard to the former, it must be remembered that statistics are ever unreliable. It is important, for example, to know if a specific epidemic is severe or not. The mild cases get well whether vaccines are employed or not, as do also paratyphoids. Concerning the clinical facts the important points are: (a) Does the patient have more resistance under specific treatment? (b) Does he relapse less? To obtain these facts each observer must state his own views, and this introduces a fallacy due to the personal element. Illustrating the mistakes that may arise, the speaker referred to a case in which the temperature fell after each dose of typhoid vaccine and yet the bacteriologists report the case to be one of paratyphoid. Sir Bertrand Dawson's view with regard to vaccines was that they are valuable if used with caution. Inoculation must be commenced early and in larger doses than are usually administered. 750 million should be given rather than the usual 200 million, increasing every second day until 500 million are reached. It is preferable to employ the larger dose in the hope of overtaking the disease, and no harm will result from the larger doses. The heterogenous army vaccine should be used, although some people prefer an autogenous vaccine. The latter is open to the objection that it may not possess the same immunising power as a heterogenous preparation of proved value. Living cultures have been tried in some quarters, and it is claimed that success has followed their employment. It is, however, a dangerous question and one which requires more thorough investigation. The number of typhoid carriers, for example, may be thus increased. In the complications of typhoid fever vaccines undoubtedly do good. This is particularly the case in periostitis. With regard to diet, all kinds of views prevail from the advocates of starvation to those who advise solid food. Concerning the latter it appears almost impossible to give solids to an individual who has no appetite and whose mouth is exceedingly dry and foul. In the few cases, however, where these measures have been employed perforation has not followed. Starvation also cannot be recommended unless distinct advantages are gained hereby. The ideal diet is milk, used as a basis, and supplemented by Benger's or Mellin's food, and beef juice. Chocolate may be given with advantage, and supplies the necessary amount of carbohydrate. When the temperature is approaching normal the amount of food should be increased. On the continent treatment by baths has a very wide application. Unless it can be proved, however, that it really materially improves the symptoms, it is a method which appears to have more disadvantages than advantage. The constant moving disturbs the patient, and unless the circumstances are such that the whole bed can be immersed in the bath it is better to employ other treatment. A continuous warm bath of 100° is good in cases associated with muttering delirium, but even in the best conditions of civil practice it is difficult to arrange. As regards the employment of alcohol, in an ordinary straightforward case it is not required. With a high pulse-rate, however, and toxæmia it is valuable, and should be given. Strychnine is useful if abdominal distension is marked and the pulse not good. Pituitrin is also well worthy of trial. The speaker concluded by discussing the

symptoms and treatment of typhoid perforation. This accident should be suspected if (a) acute pain suddenly develops in the abdomen, followed by distension, rigidity, and a rising pulse; or (b) if the pulse is rising and the patient is exceedingly clear in mind. In the latter case pain may be little and distension absent. Two such cases had occurred at Wimereux. As regards treatment, if a surgeon is available it is best to operate. If, however, the site of perforation cannot be reached quickly the proper course is to leave the patient alone and administer morphia. It does not follow that all such patients die. Several instances are on record where the perforation has been closed by local adhesions.

Colonel Sir WILLIAM LEISHMAN, continuing the discussion, observed that during the six months the war had lasted only 605 cases of typhoid fever had occurred in the British troops and 25 in the Indian. In other words, about only half a battalion had been incapacitated from this cause. Of 505 of these cases 72 had been fully protected by inoculation (two doses of vaccine within two years), 113 partially protected, and 320 uninoculated. These figures proved once and for all the value of protection. It was impossible, for obvious reasons, to publish the total number of men that had been inoculated, but he could say with conviction that from 80 to 90 per cent. of the army were now protected. With regard to the question of mortality no death had occurred in the fully protected patients, one only in the partly protected, and 45 in the uninoculated cases. The influence of inoculation upon the severity of the case was also made evident by the figures obtained during the last six months. The available material might be classed as follows:—

	Inoculated (40).	Uninoculated (106).
1. Severe	9	56
2. Average	17	34
3. Mild	9	8
4. Early	5	8

Turning to the question of vaccine treatment, the speaker admitted that nothing was harder to answer as to whether vaccine treatment in typhoid was a success or not. In a series of 146 cases 94 had been treated by vaccines. The results might be given as follows: Good, 28; doubtful, 30; no benefit, 17; too early to judge 19; total, 94. The large majority of cases have not had a fair chance of proving the value of vaccines. They are seen too late, very large numbers not being treated until the end of the second or well into the third week. Also, many of the patients treated by typhoid vaccines have later proved to be paratyphoid infections. Furthermore, the cases treated by vaccine are usually the most severe, the milder conditions recovering without resort to these measures. As a result of this no controls are available. With regard to Sir Bertrand Dawson's suggestions on the use of mixed vaccines of typhoid and paratyphoid he (the speaker) said that the matter had been under consideration, but personally he had been against the same on two grounds—(1) increased danger; and (2) the possibility of damaging the typhoid element in the vaccine. Referring to paratyphoid B he agreed that many mild cases of this type were undoubtedly being missed. The majority of them remained in stationary or clearing hospitals. As Sir Bertrand Dawson had remarked, paratyphoid B had hæmorrhages and relapsed, but perforation very rarely occurred, if at all. Concerning Widal's reaction, the speaker said that if the bacteriologist had the time at his disposal to apply the test thoroughly, it was capable of giving very valuable information. The anomalies that from time to time occurred could be explained. For example, with regard to fluctuation, it must be remembered that the height of agglutination is only a rough index of the amount of protective substances in the blood. These substances vary in cases of severe infection—e.g., agglutinins disappear just before death. It is therefore not to the discredit of the test that these variations occur. He (the speaker) was glad to hear Sir Bertrand Dawson lay stress upon the importance of blood cultures. As a matter of fact, all cases are now being dealt with systematically on these lines, and the number of occasions upon which bacteria have been found in the cultures has been considerable. Probably the number of organisms present in the blood varies on different days of the disease, as is the case with plague. With regard to the previous speaker's suggestions of obtaining blood from the spleen or liver, French physicians had

made investigations concerning the former organ but had since abandoned the method, which was hardly justifiable. It was not difficult, all the same, to obtain blood from the spleen, and in kala-azar from 200 to 300 cases had been investigated without danger or mishap. Hepatic puncture would probably be of little use owing to the difficulty of obtaining hepatic blood. Unless the tissue is definitely broken up the blood obtained would be that circulating and not true hepatic. In conclusion, Colonel Leishman referred to the value of autogenous *versus* heterogenous vaccines in the case of typhoid fever. He agreed that so far the ideal vaccine has not been reached. The army vaccine has given very good results in the past, and he preferred to employ a preparation of proved value than one of uncertain worth. Rawling's vaccine was as good as any, and when a good antigen was known it was inadvisable to waste time in using a possibly inferior strain. The question of employing living cultures was undoubtedly an important one. Lieutenant Rowlands, at No. 10 Stationary Hospital, had used living cultures upon four occasions and the attacks seemed to have been aborted. Further trials were needed before a definite reply upon this matter could be given.

Lieutenant HAROLD WILTSHIRE said that owing to the very short period he had been in charge of the typhoid cases in Rouen he was unable to speak at length. At No. 12 General Hospital 68 cases of enteric fever had been treated, and of these 10 had died. With regard to the value of preventive inoculation, the figures from Rouen had been included in Sir William Leishman's report. It was a matter of extreme difficulty to ascertain in many instances whether a man had been inoculated or not. The army pay book was not always available, and in some instances men said that they had been inoculated when the reverse was the case. The effect of inoculation upon the Widal reaction urgently requires investigation. In practice the test is only pushed to the degree of diagnosis and not to its highest dilution. Blood cultures had been taken in 35 cases. The method was a very useful one, and was now the routine. In discussing the points of diagnosis, Lieutenant Wiltshire laid special stress upon the slow pulse, the great help derived from the tongue, the slightly full and tympanitic abdomen, and a gurgle in the right iliac fossa. As illustrative of the difficulties of diagnosis he referred to the abortive and ambulatory types of the disease and quoted cases which were only proved by conducting a bacteriological investigation of the faeces. He suggested that possibly the clinical aspect of the disease is modified by inoculation, since so many of the cases resembled influenza. He was inclined to the belief that, as a rule, when an inoculated patient gets typhoid he was a mild but typical case. As regards vaccine treatment, out of 68 cases, 48 had been treated by vaccines, and of the latter 45 had been heterogenous and of the "stock" variety. In 21 no improvement was noted and in 24 it did good. The dosage had been 125 million, working up to 500 million. No ill effect had been seen from larger doses. Late in the disease vaccines may give an increased possibility to hæmorrhage, but as a rule in practice this symptom occurs so late that vaccines are not required. The time for vaccine treatment is undoubtedly the first fortnight, and the speaker suggested that it should be combined with anti-endotoxic serum. The vaccine will kill the bacteria and the serum will neutralise the toxin. Concerning drugs, urotropine in large doses had been tried, but so far no improvement had been noted. Salol and other antiseptics also appeared to be useless. In order to prevent the foul condition of the mouth Lieutenant Wiltshire recommended the employment of chewing gum. He was accustomed to prescribe it in every case where nutrient enemata were indicated.

Major A. B. SMALLMAN said that case mortality is the true test of the value of vaccine treatment and this had been amply proved by the figures laid before the meeting. He referred to a series of 235 cases treated in South Africa, some by heterogenous and some by autogenous vaccines, but in both the total case mortality was very low. With regard to the risks of hæmorrhage from vaccine treatment data were required as to the dosage employed. It was possible to overload a patient. As regards local conditions the value of vaccine treatment was very striking if full-strength doses were employed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

X Ray Appearances of Some Common Disorders of the Stomach.

A MEETING of this society was held at the West London Hospital on March 5th, Dr. F. S. PALMER, past President, being in the chair.

Dr. REGINALD MORTON read a paper on the X Ray Appearances of Some Common Disorders of the Stomach, which was illustrated with a number of lantern slides. He emphasised the necessity for keeping all the conditions during an X ray examination of the digestive organs as nearly normal as possible. The patient should be prepared by giving a laxative the second night before the examination, and the opaque meal was to take the place of the usual breakfast. This meal should be of some ordinary food such as porridge or bread-and-milk, and the substance used to make it opaque to the X rays quite inert and free from any possible chemical or physiological action, the two best materials being bismuth oxychloride and barium sulphate. Bismuth carbonate neutralised the gastric juice and should not be used. After indicating possible sources of error in observation, Dr. Morton first showed the appearances of a normal stomach, antero-posteriorly and laterally, in a young healthy adult, and explained how the appearances of this differed from our original ideas of the size and shape of the stomach—the absence of muscular tone being the chief factor on the operation table and post mortem. He then demonstrated how easily the form and position of the organ were influenced by mechanical, reflex, and sensory impressions, proving it to be a very sensitive part of the digestive system. Turning to the pathological stomach, he showed instances of atony, one of the most common abnormalities, sometimes existing alone, but most often in association with gastric ulcer or pyloric obstruction or both. The spasmodic constriction of the circular fibres commonly associated with gastric ulcer was shown in several cases and the method of distinguishing the spasmodic from the organic contractions explained. One case in particular showed the truth of the epigram which says, "The most frequent seat of gastric ulcer is in the right iliac fossa." The stomach showed the presence of at least two ulcers as well as some degree of pyloric obstruction. Suspicion rested on the appendix, which was found to be catarrhal and was removed by Mr. Aslett Baldwin. A radiogram made five months later showed a normal stomach. Cases exhibiting different stages in the development of the condition of hour glass stomach were shown, those of the organic type being both various and striking. Of these the X ray examination gave a large amount of information as to the relative size of the two sacs and their condition—an important point in the matter of operative procedure. In most cases gastro-enterostomy was the only possible operation but where the lower sac was seen to be acting fairly well and no indication of pyloric obstruction, as sometimes happens, the question of joining the two sacs by a gastro-gastrostomy should be considered. An effort should be made to preserve the gastric digestion where the circumstances made this possible. Dr. Morton suggested this as a suitable subject for discussion, and he hoped some evidence as to the condition of patients who had undergone gastro-enterostomy several years previously might be forthcoming. In conclusion, he explained how any paper dealing with one part of the digestive system was bound to be incomplete, so intimately were the various parts linked together through their nervous mechanism; it was impossible to study the disorders of one part while ignoring the others. His object was to help those who were not radiologists more accurately to visualise the various disorders of the stomach as they occur under the ordinary conditions of everyday existence, and he hoped he had met with at least some small degree of success.

Dr. PALMER, after speaking of the interesting character of the paper and the clearness of the radiographs shown, went on to say how important had become the X ray method in the diagnosis and treatment of gastric affections, and gave instances where it had proved the existence of disease quite different from what the clinical signs and symptoms indicated. He would like to ask Dr. Morton if it was not the case that barium gave a better shadow than bismuth.

Dr. STANLEY MELVILLE paid a warm tribute to the excellence of the radiographs illustrating the paper, and said that he considered the use of aperients inadvisable in the preparation of the patient for the X ray examination, and instanced how the use of liquid paraffin could quite upset any idea of stasis being present unless its use was discontinued a week or ten days before the examination. He quoted a case similar to one stated in the paper which showed how difficult it was at times to make a clear diagnosis, but fortunately such cases were gradually becoming more infrequent as our knowledge of the subject increased.

Dr. E. ARTHUR SAUNDERS, while admitting the value of the X ray method in the diagnosis of digestive conditions, considered that they should be careful not to attach too much importance to those appearances, since it occasionally happened that the middle portion of the stomach was congenitally narrowed and yet performed its function normally; also it was well known that many cases of undoubted stasis in some part of the digestive tube did quite well with the use of paraffin and without surgical interference.

Dr. MORTON, replying to Dr. Palmer, said that he had made many experiments with different salts of bismuth and barium to determine their relative opacity to the X rays. Speaking generally, it was found that barium was less dense than bismuth, and this was only to be expected considering that opacity to the X rays was purely a matter of atomic weight, that of bismuth being much higher than barium. A layer of barium sulphate had to be about 50 per cent. thicker to give an opacity equal to a bismuth compound. In the preparation of opaque meals this was compensated for by using a correspondingly greater amount of the barium salt. Replying to Dr. Melville, Dr. Morton said that of course if the patient had been in the habit of taking paraffin it should be discontinued for some days previously, but an ordinary aperient should be given to clear out the colon so that the progress of the opaque meal could be free from this form of interference. He quite agreed with Dr. Saunders as to the need for caution in estimating the importance of X ray appearances.

ÆSCULAPIAN SOCIETY.

Jaundice.

A MEETING of this society was held at the Metropolitan Hospital on March 5th, Dr. DAVID ROSS, a past President, being in the chair.

Dr. W. LANGDON BROWN read a paper on Jaundice, in the course of which he said: Jaundice is a classical example of striking symptoms of varying significance due in all but one type to obstruction of a bile-duct. The obstruction may be: 1) within the tube, due to gall-stones, catarrh, or parasites; 2) in the walls of the tube, due to stricture, atresia, or new growth; and (3) outside the tube, due to pressure from new growth in the head of the pancreas or lymphatic glands. Cases without obvious obstruction give rise to much controversy. A patient may be born jaundiced or become so soon after birth, as in cases of congenital cholemia or acholuric jaundice. Absence of pigment in faeces indicates obstruction, but the presence of excess of fat in the stools due to pancreatic disease may completely mask the presence of bile pigment and simulate the clay-coloured stools of jaundice. In many cases of jaundice suitable methods of extraction will prove the presence of pigment. This is so in the case of gall-stones more than in new growth and may be of diagnostic value. We can in certain cases of fatty stools determine whether the pancreatic juice or bile is at fault. If the excess of fat is due to pancreatic defect, unsaponified fat will be in excess of saponified. If the excess of fat is due to loss of bile saponified fats will be in excess because they cannot be adequately absorbed. Wasting occurs on this account. Bile is a natural stimulant of peristalsis, and so its absence constipation occurs. Bile, though claimed as an antiseptic, cannot keep itself from putrefaction. As a matter of fact, the bile salts and fats are so slowly absorbed that they coat over the proteins, which therefore undergo bacterial decomposition instead of quick assimilation. Hyperchlorhydria is a common accompaniment of jaundice, particularly if associated with pain. Bile pigment appears in the urine before it can be detected in the conjunctiva, and disappears from the urine last. Bile salts may be found

in the urine before bile pigment by the method of Matthew Hay. Flowers of sulphur placed on urine sink in their presence. The majority of cases of jaundice do not show bile salts in the urine, and those which normally enter the bowel are reabsorbed and used over again up to ten times. Urobilin is absent from urine in complete obstruction of the bile ducts, as it is a reproduction product formed by bacterial action on bile pigment in the bowel. Bile reaches the blood through the lymphatics and the thoracic duct. This may account for the appearance of bile pigment in the blood serum two hours after ligation of the bile duct, and therefore before it appears in the conjunctiva or skin. Anæmia is not typical of ordinary jaundice and so differentiates from congenital family cholemia. Small hæmorrhages may occur on the skin produced by scratching excited by pruritus. One of the most definite results of jaundice is bradycardia, with a low-pressure diastolic pulse. Toxicæmic jaundice will be accompanied by headache, delirium, and ultimately coma. Bile pigment appears in the skin soon after it does in the conjunctiva. The well-known lemon tint of pernicious anæmia is associated with a pearly white conjunctiva. Itching is troublesome, and the best treatment is by thyroid extract. Saliva, tears, and milk are not bile-stained. Sweat is said to be, but this is exceptional. After the use of pilocarpine this may be so. Nasal and bronchial mucus is not tinged with bile, nor is expectoration in bronchitis unless pneumonia or oedema of lung should occur. In cases of mastitis the milk is also stained. The absence of bile salts from the intestine constitutes the most important symptoms of jaundice—stearrhoea, wasting, intestinal putrefaction and constipation; their presence in the blood, bradycardia, headache, depression, pruritus, and sometimes hæmorrhages. Treatment: Soft carbohydrates and green vegetables promote flatulence. The fats, while diminishing the secretion of acid in the gastric juice, depend on bile for their absorption, and if not absorbed they increase intestinal putrefaction by coating over the proteins. Moreover, their influence in producing obesity must not be forgotten. The practical deductions from these considerations are: 1. White fish, eggs, cheese, and mutton may be allowed, while soups, broths, liver, kidney, sweetbreads, and rump steak should be forbidden until the hyperchlorhydria is checked. 2. Dry forms of carbohydrate, such as biscuits, rusks, and toast, are preferable to bread and ground rice puddings and the like, because they demand mastication before they can be swallowed, and therefore undergo a considerable degree of digestion by the saliva. 3. Sweets can be selected from jelly, egg custard, omelette, junket, and stewed fruit. 4. At first vegetables had better be forbidden altogether, for though cellulose is an aid to peristalsis it promotes flatulence. As the patient's intestinal condition improves this rule may be gradually relaxed. 5. Fats in the form of butter, cream, or fat meat should only be allowed in small amounts, for the reason given above. It is important that water should be drunk to prevent inspissation of the bile. Patients do not care to be told to drink water from the tap, preferring, as of old, the waters of Abana and Pharpar. It is well, therefore, to select a spring which is mildly aperient, slightly alkaline, and one which is not too highly mineralised. Milk is usually recommended as the mainstay, but owing to its comparative richness in fat it is not really suitable, and is often much disliked by the patient. It is preferable to give barley water with the white of an egg, and a teaspoonful of plasmon or somatose to each half-pint, flavoured with lemon. Tea is usually forbidden, though it is difficult to see on what grounds. Jaundiced patients often crave for it, and if made in the Russian fashion without milk but with a slice of lemon in it, it seems free from objection. If the practitioner feels reluctant to abandon milk it should be separated or thoroughly skimmed to get rid of as much fat as possible, and then a grain of sodium citrate added to each ounce of milk to diminish curdling. Benger's food, calves' foot jelly, and lemon sponge can usually be taken without difficulty. Mineral waters of an alkaline type may be drunk freely. When the bile pigment has returned to the faeces the patient feels much better though still jaundiced. He can now get up and the diet should be cautiously increased. There is often considerable depression during convalescence, for which strychnine and calumba may be given. Dilute nitro-hydrochloric acid in 10-minim doses is often advised, but should not be given until all signs of obstruction have passed off.

Reviews and Notices of Books.

Materia Medica: Pharmacy, Pharmacology and Therapeutics.

By W. HALE WHITE, M.D., F.R.C.P. Lond., M.R.C.S. Eng.
Fourteenth edition. London: J. and A. Churchill. 1915.
Pp. 712. Price 6s. 6d. net.

THE consideration of the fourteenth edition of a student's text-book on *materia medica* ordinarily affords little scope for critical faculties. The author presumably has long since decided upon the range of the information demanded by his readers, and has, no doubt, found from experience an appropriate mode of selection and presentation of material culled from judicious study of recent literature. After the form of presentation has been determined there is little scope for the display of originality; accordingly it only appears to be necessary to note the incorporation of new material which has resulted from recent advances in research, or from authoritative recognition in the new British Pharmacopœia.

With regard to the former, much interest attaches to the section called in the table of contents "Pharmacopœial Organic Animal *Materia Medica*," but in the text more correctly designated "pharmacopœial substances derived from the animal kingdom." Even this title is not quite right, since many of the substances dealt with are certainly not pharmacopœial, though they are used medicinally; in each instance, however, the unofficial character is duly noted. In this section are included several of the more important sera and vaccines, and in some instances there are a few brief notes concerning their mode of preparation. The mode of administration and the indications for their employment are given in greater detail and are likely to be of service to young practitioners. Of the very large number of unofficial compounds which are dealt with in this book it may be sufficient to mention the following: methyl chloride, anestyle, ethyl bromide, medinal, adalin, salipyrin, citrophen, pyramidon, tolpyrin, exalgin, methylene blue, orthoform, antikamnia, and omnopon (which, by the way, is incorrectly termed "panopton"). The notes relating to these and to similar new compounds are very brief, but they will serve to identify the substances without referring to other sources of information. Some four pages are devoted to unofficial compounds of arsenic, including salvarsan and neosalvarsan. Clear directions are given for the mode of administration of these preparations, and the therapeutic uses are discussed. Notwithstanding all that has been written of its value, the author thinks that sufficient time has not yet elapsed for us to be sure that syphilis is permanently cured by salvarsan, and in spite of its employment he advocates giving subsequently a course of mercury for two or three years.

The inclusion of new official information has been very deftly accomplished. Frequently it has been found possible to save space by brief reference under a former article so as to avoid repetition of many pharmacological and therapeutic details. In other instances it has not been necessary to effect any change, since the official mantle is extended only over drugs which have already found favour with the medical profession, and accordingly these in their unofficial stage have been previously dealt with in former editions. In the preface the

author has given a series of tables showing the official additions and omissions, and has also indicated the chief alterations in strength and in nomenclature. Incidentally it may be mentioned that he is in error in stating that the British Pharmacopœia gives an official abbreviation for the name of each official substance and preparation. The list to which he refers indicates the abbreviations adopted in the index; they do not form part of the official monographs.

In general terms it may be said that this new edition is a worthy successor to former editions; considerable care has been taken not to overload with detail of doubtful value concerning new remedies; exaggerated statements are avoided, and the author maintains an impartial spirit through which a vein of scepticism may often be discerned. This exhibition of restraint is a welcome characteristic of this book, and is no doubt one of the secrets of its success.

Medical Diagnosis.

By ARTHUR LATHAM, M.A., M.D. Oxon., F.R.C.P. Lond., and JAMES A. TORRENS, M.B., B.S. Lond., M.R.C.P. Lond. With 74 illustrations, 19 in colour. London: J. and A. Churchill. 1915. Pp. xii. + 641. Price 15s. net.

DURING the last few years several text-books, large and small, of medical diagnosis have been published, and speaking generally have been constructed upon one or other of two separate plans. One method sets out with the various physical signs and symptoms that may be exhibited by the patient; and under the heading of each of these gives an account of, and the method of distinguishing between, the different diseases in which each sign or symptom may occur. French's "Index of Differential Diagnosis" (reviewed in THE LANCET of Nov. 9th, 1912) affords an excellent example of books of this kind. The second plan of campaign, adopted, for example, in W. M. Stevens's "Medical Diagnosis" (reviewed in THE LANCET of April 22nd, 1911), is to take the different diseases from which man suffers as headings, and under each heading to detail the various means of diagnosing each disease from others that may be confused with it. This is the plan adopted by Latham and Torrens, and we may say at once that they have carried it out with no small measure of success.

The book is divided into six parts, in which are discussed certain specific infective diseases and helminthiasis, diseases of the blood and allied conditions, diseases of the heart, lungs, and alimentary tract, diseases of the pancreas and kidney, diseases of the nervous system, and, finally, certain diseases of the skin. The information given under the heading of each disease is well arranged, and by the use of subheadings and different founts of type is set out clearly so as to catch the eye. The authors have been sparing in their use of words, with the result that the text achieves a brevity and directness for which medical students who consult the book will be grateful. At the same time little that is essential seems to have been omitted, although it has naturally not been possible to include in a volume so moderate in size the rarities of disease that very properly find their place in the much larger text books of medical diagnosis mentioned above. It is inevitable that a few blemishes should appear in the text of a volume covering so large an area as this. "Typhoid spine" is described (p. 18) as neuritis or neuralgia without any mention of the osteitis or periostitis that so often occurs with it.

tuberculous meningitis is said (p. 86) to be rare in the first year of life, yet the Registrar-General's returns for 1910, for example, show that it occurred in 13 per 10,000 of the children born; in the excellent chapter on the examination and analysis of urine no mention is made of the fact, established by Mörner, that traces of albumin (up to perhaps 50 milligrammes per litre) appear in normal urine. Many of the illustrations are admirable. The microphotographs borrowed from Slater and Spitta's Atlas, very well reproduced, are indeed more informing than the explanatory text that has been provided to accompany them. Abundant reference to laboratory methods of diagnosis is made throughout the volume, with the result that the reader is placed in command of all the more practical means of expert diagnosis.

The authors set out with the intention of writing a book in which medical diagnosis should be considered from the points of view of both clinical medicine and the clinical laboratory, for the benefit of the medical student and the medical practitioner. They are to be congratulated upon the result of their labours, which may be recommended to readers of both these classes.

Anæsthesia.

By JAMES TAYLOR GWATHMEY, M.D. New York, in collaboration with CHARLES BASKERVILLE, Ph.D., F.C.S., Professor of Chemistry in the College of the City of New York. With 283 illustrations in the text. New York and London: D. Appleton and Co. 1914. Pp. 945. Price 25s.

As a comprehensive work of reference in which to find all kinds of transatlantic achievement in relation to anæsthetics this compilation is likely to hold for long a foremost place. It is more in the nature of a "system" of anæsthetics than of an individual compilation, the list of contributors containing no less than ten names. It is noteworthy that not only Dr. Gwathmey's co-editor but also his contributors are none of them professed anæsthetists, but all surgeons, physicians, dentists, or chemists.

It is the first inclination in perusing a work of this kind produced out of Great Britain to reflect upon its probable nature had it been essayed here, and the idea readily occurs to one that a larger proportion of its pages would have been entrusted to anæsthetists pure and simple. The result would have been probably less interesting if of more practical detail. The next comparative reflection is this, that by the practice in America of doing most operations in hospitals the American anæsthetist is at a great advantage over his British *confrère*, inasmuch as portability and complexity of apparatus need hardly be taken into account. Consequently we find an elaboration of apparatus and of technique in American practice which is of necessity absent in these islands, at any rate from private practice. Whether such elaboration is always of service is another question, but at least it is a great advantage that no question of mere convenience should have to be considered when the adoption of some superior method is at stake. Thus the practice of warming and vaporising all anæsthetics before their admission to the respiratory passages is strongly recommended, and evidently largely employed by Dr. Gwathmey, and this, like the prolonged administrations of nitrous oxide and oxygen also in favour in America, requires extensive apparatus. Two chapters are devoted to colonic anæsthesia, with a very long description of apparatus; to mental influence and

hypnotism in anæsthesia; to therapeutic uses of inhalation anæsthetics, and to the medico-legal status of the anæsthetist. The sequestration method of anæsthesia, and electric analgesia, sleep, and resuscitation are also fully dealt with.

It will be readily understood, therefore, that the editors have produced a volume of wide interest to the student of anæsthesia, and the portion of the book for which Dr. Gwathmey is himself responsible provides practical information of a detailed character such as would be expected of an anæsthetist with his extensive experience. In addition he has been at the trouble to collect a large number of statistical data from which a table of conclusions as to the safety of various agents and methods is drawn up, and he has provided an unusually complete list of all the substances that can be used for the production of any kind of anæsthesia.

The Acute Abdomen.

By WILLIAM HENRY BATTLE, F.R.C.S. Eng., Senior Surgeon to St. Thomas's Hospital; formerly Joint Lecturer on Systematic Surgery and on Practical Surgery to St. Thomas's Hospital Medical School, &c. Second edition, enlarged and illustrated. London: Constable and Co., Limited. 1914. Pp. 295. Price 10s. 6d. net.

WE are glad to see the appearance of a second edition of this work, whose utility cannot be in question, for it helps to elucidate some of the most difficult problems with which the surgeon can be confronted. The great power possessed by the modern surgeon in dealing with acute abdominal diseases depends mainly on early diagnosis and treatment, and to those who have not had much experience in this branch of surgery a work such as this should prove very helpful.

The surgery of the acute abdomen has become simplified, and we agree thoroughly with the author when he says that the methods to be described should be as simple as possible, so that no practitioner need fear to make an attempt to save a threatened life because he has not some particular clamp, bobbin, or brand of catgut in his possession. The chief additions to the present edition are those on the planning of abdominal incisions and on injuries to the abdomen. A valuable feature is to be found in the histories of cases. These are very instructive and give the reader much clearer ideas than generalised descriptions of symptoms would have given. There are naturally many points in the book that invite discussion, but it must be acknowledged that the views put forth by Mr. Battle are eminently reasonable and afford evidence of his wide experience.

A Manual of Physiology, with Practical Exercises.

By G. N. STEWART, M.A., D.Sc., M.D., Professor of Experimental Medicine in Western Reserve University, Cleveland. Seventh edition. With coloured plate and 467 other illustrations. London: Baillière, Tindall, and Cox. 1914. Pp. xxiv.-1132. Price 18s. net.

WE reviewed the sixth edition of this now standard work in THE LANCET of Feb. 11th, 1911. It may be taken for granted that any well-approved text-book on such an ever-progressive subject as physiology which has reached its seventh edition during a period of 18 years is one which by its sterling qualities and the scope and usefulness of its subject-matter has met the requirements both of medical students and practitioners who wish to keep up to date. More especially is this the case when the comparatively new subject of biochemistry is making such important and withal practical strides. Obviously this consideration

has impressed the author, for he has practically rewritten the chapter on metabolism as well as that on the allied subject of the actions of enzymes, while blood gases are considered in much greater detail than in previous editions. Additions have been made to most of the other subjects, while the important newer work on the relation of heat production and the chemical changes in muscular contraction has been taken account of. The longer chapters—we think with great advantage—have been broken up into sections, the number of illustrations has been increased from 450 in the sixth edition to 467 in the present edition, and the number of pages from 1064 to 1132.

Very decided improvements in and substantial additions to the chapters on blood have been made, including the newer facts on fibrin formation in normal and hæmophilic blood revealed by the ultramicroscope. The ingenious "Vivi-diffusion" apparatus of Abel is figured and described. A new table with wave lengths of the spectra of hæmoglobin and its derivatives replaces a simpler form. We have carefully compared this edition with the last one, and we find additions and improvements in all subjects. A most useful addition is the list of the best known enzymes in the body. Some rearrangements have been made whereby formation of lymph comes after absorption and before excretion. It appears that in the males of certain aquatic birds erection is due to the filling of the corpus cavernosum not with blood but with lymph. The secretion is under the influence of nerves. Some interesting comments and suggestions are made on vitamins. The diagram of Du Bois-Reymond's inductorium leaves something to be desired. Obviously the title "possibility of recovery of muscles after rigor" is a better one than "the recoverability of rigor." Many additions and some excisions have been made in the chapter dealing with the central nervous system. Less than three pages suffice for the autonomic nervous system.

We have no hesitation in recommending Professor Stewart's "Manual of Physiology" as at once comprehensive, trustworthy, and thoroughly up to date on every subject with which it deals.

MISCELLANEOUS VOLUMES.

SEVERAL books on nursing, both general and under special conditions, claim attention.

The first of these, *Notes on Nursing*, by FLORENCE NIGHTINGALE (New edition. London: Harrison and Sons. 1914. Pp. 160), is a reprint of the edition of 1861, which contained Miss Nightingale's latest corrections. The first edition had appeared in 1859, and "was instantly recognised," as Sir Edward Cook says, "by the leaders in medical and sanitary science as a work of first-rate importance; as one of those rare books to which, within their range, the term epoch-making may rightly be applied." It need not be said that the conditions of hospitals, and of nursing, and the general education as well as the professional training of nurses, are at the present day very different from what was the case then. Nevertheless this book "can never be out of date, and no one who has ever read it has found it dull." Miss Nightingale herself said that the notes were meant "simply to give hints for thought to women who have personal charge of the health of others." This really applies to almost every woman, in whatever station of life she may be, or whatever be her occupations. It may be safely said that hardly anyone can read the book without learning something, and no one can read it without pleasure. Though originally published as far back as 1859, in what we are accustomed to consider the dark ages before sanitation was understood, or indeed even much thought about, the very first chapter in the book deals with ventilation, showing that the author was even then fully alive to the importance of fresh air, much more so than was the case with many physicians. The subjects of health in the house,

food and its administration, observation of the sick, &c., are considered, and cleanliness and fresh air insisted on over and over again. The details of nursing practice in 1915 must, of course, whether in medical or surgical cases, be learned from an instructor versed in modern methods; but the real meaning of nursing, its principles, the spirit in which it should be carried out, and the qualities of intelligence and disposition that are needed for the proper exercise of the calling can never be better learned than from this book. To the rising generation Florence Nightingale must not become a mere *nominis umbra*. To those who actually knew her, and to those who have known the extraordinary influence that she exerted on her charges, colleagues, and subordinates, and on the most cultivated and intellectual of her contemporaries, the re-issue of this little book will come as a welcome reminder. To all concerned with the care of the sick or wounded in any way it will be a pleasure and a profit to possess it. The story of the "Lady with the Lamp" cannot be too widely known, nor her example too closely followed.—A somewhat pretentious work is *Practical Nursing, a Text-book for Nurses*, by AMY C. MAXWELL, Superintendent of Presbyterian Hospital School of Nursing, and AMY ELIZABETH POPE, formerly Instructor in Presbyterian Hospital School of Nursing. (Third edition. Illustrated. London and New York: G. P. Putnam's Sons. 1914. Pp. 873. Price 7s. 6d. net.) After a short initial chapter on the qualifications for a nurse and professional etiquette, a rather sudden plunge is made into bacteriology, a short résumé of the whole subject, including disinfection, being given in Chapter II. The next chapter deals with the composition of air and ventilation, after which practical nursing is entered on, with instructions as to the care of a ward, bedmaking, and the care of the patient. A description of symptoms and signs in disease, and of the use of therapeutic methods, medicines, and enemata, follows; after which the care of operation cases, operating room technique, and surgical emergencies are dealt with. Two hundred pages are devoted to a synopsis of the more important diseases and the subject of food generally. The authors have been industrious in producing a compilation on pretty well all the subjects that a nurse needs to be instructed on, but it cannot be said that the endeavour to compress medicine, surgery, and dietetics into 200 pages in a nursing manual has been successful. A considerable number of doubtful statements are met with, and there is lack of order and arrangement. To say that "cholera occurs principally among the natives of India and China" (p. 678) is strictly true, but misleading. The portion of the book dealing with nursing is adequate and trustworthy.—*Modern Medical and Surgical Nursing for Probationers* (London: Poor-law Publications Company. Pp. 228) consists of selected lectures by C. SEYMOUR YAPP, matron of the Poor-law hospital at Ashton-under-Lyne, and contains a more complete and thorough course of instruction than is usually afforded in nursing manuals. It consists of 47 lectures delivered to the first, second, and third year nurses. The author has evidently great experience, and is able to express her views clearly and concisely. The point that distinguishes this book from the generality of nursing manuals is that it enters more into detail, and is more comprehensive than is usually the case. Nothing in the whole range of nursing is omitted, and there is not a sentence that is redundant. It is to be highly recommended. Theoretically, perhaps, there should be no distinction between the ethics of general and professional life inasmuch as the standard of moral conduct ought to be founded on what is known as the Golden Rule. In practice, however, just as the standard is modified according to certain individual relationships, so in the specific application of ethics to professions circumstances may modify the rules that men apply when dealing with others outside the ordinary relationships of man and man. The special ethics of the nursing profession have received much less attention from writers than those of the medical profession, and Dr. T. PERCY C. KIRKPATRICK, the Registrar of the Royal College of Physicians of Ireland, is to be congratulated on the sympathetic and able way in which he deals with the subject in a lecture on *Nursing Ethics*, recently published by the Dublin University Press. He strikes the keynote of the lecture when he says: "A high standard of nursing ethics involves a high standard of general ethics, or, in other words, a good nurse must first be a good woman." This

truth has been admirably exemplified in the life of Florence Nightingale. She it was who made nursing a real profession and caused the extinction of the low type of nurse so prevalent before the Crimean War. Dr. Kirkpatrick, after briefly sketching the history of nursing in this country, said that when hospitals began to spring up in both England and Ireland the nurses, generally drawn from the lowest social class, were looked upon merely as servants. After discussing the principles which should guide the conduct of a nurse in the hospital, where, besides acquiring a technical knowledge of her profession, she should imbibe those ethical principles which are to guide her through life, and where she is in somewhat the position of a hostess ministering to her guests, Dr. Kirkpatrick passes on to the status of the private nurse, between whom and her patient the position of hostess and guest is reversed. Attention to detail, thoroughness,

cleanliness, loyalty, and, above all, sympathy are emphasised. The nurse who lives up to principles laid down in this useful brochure can hardly fail to uplift the standard of her profession.

AMY E. POPE, one of the authors of a work noticed above, has also produced *A Medical Dictionary for Nurses* (London and New York: G. P. Putnam's Sons. 1914. Pp. 288. Price 3s. 6d. net). The technical terms in medicine and surgery are shortly explained; many non-technical terms in ordinary use, such as breath, capacity, inadequate, and so forth, are defined somewhat unnecessarily, and others, such as toxoid, toxon, and toxophore group, seem to have no connexion whatever with a nurse's work. Such criticism is, however, applicable to many technical dictionaries, and the present volume is handy and useful.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION:

Summary of Reports for Month ending Dec. 31st, 1914.

1	2	3	4	5	6	7	8	9	10	11	12
Place.	Correspondent.	Rainfall in milli- metres.	Metric tons of deposit per square kilometre during month.

* No returns.

Col. 4 includes all matter insoluble in water but soluble in CS₂. Col. 5 includes all combustible matter insoluble in water and in CS₂. Col. 6 includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 91b. per acre; (b) 2.56 English tons per sq. mile; (c) one gramme per sq. metre; (d) 1/1000 millimetre of rainfall (see Col. 3).

The analytical work involved in these returns was undertaken respectively by J. F. Liversidge, F.I.C., Birmingham; Harry Hurst, B.Sc., F.I.C., Bolton; F. Southerden, B.Sc., F.I.C., Exeter; A. R. Tankard, F.I.C., Kingston-upon-Hull; W. H. Roberts, M.Sc., F.I.C., Liverpool; S. A. Vasey, F.I.C., Director, THE LANCET Laboratory (London Meteorological Office collections); J. H. Coste, F.I.C. (Embankment Gardens, Finsbury Park, Ravenscourt Park, Southwark Park, Wandsworth Common, Victoria Park collections), London; F. L. Teed, D.Sc., Golden-lane, London, E.C.; C. C. Duncan, F.I.C., Malvern; E. Knecht, Ph.D., M.Sc., Cheadle, Davyhulme, Fallowfield, School of Technology, University, Whitefield (Manchester collections); J. J. Dunn, D.Sc., Newcastle-on-Tyne; Professor W. P. Wynne, Attercliffe Burial Ground, Hillsborough Park, Meersbrook Park, Weston Park (Sheffield collections); S. H. Davies, M.Sc., York; J. W. Biggart, F.I.C., Greenock; A. Scott Dodd, B.Sc., F.I.C., and R. M. Clark, B.Sc., Leith and Paisley respectively; Messrs. R. B. Tatlock and Thomson, Coatbridge. The correspondents referred to in col. 2 are for the most part public health authorities.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

ANTISEPTIC PASTE.

(MESSRS. CHAS. ZIMMERMANN AND CO. (CHEMICALS), LIMITED,
9 AND 10, ST. MARY-AT-HILL, LONDON, E.C.)

Sir Watson Cheyne in his Hunterian oration before the Royal College of Surgeons of England, which was published in our columns of Feb. 27th, referred to the use of phenol pastes in the treatment of wounds in war. We have received from the above firm a sample of the paste made to some extent on the lines there suggested. It contains 25 per cent. of pure cresols combined with a bland non-irritant base. It is of medium consistency, and is conveniently used from a collapsible tube. Of course, the percentage of active antiseptic can be varied, while also the consistence of the medium can be made firmer or thinner according to requirements. In our analysis we succeeded in isolating just 25 per cent. of cresols, the amount which is claimed to be present.

AQUAPERIA.

(CAMWAL, LIMITED, 112, PEMBROKE-ROAD, CALEDONIAN-ROAD,
LONDON, N.)

This aperient water is introduced to take the place of the foreign natural bitter waters now stopped from coming into this country. According to our analysis it contains chiefly the sulphates of magnesium and sodium together with some common salt and carbonate of soda. The quantities were as follows, representing grammes per litre: magnesium sulphate, 15.75; sodium sulphate, 12.40; sodium chloride, 2.34; and sodium carbonate, 1.06, giving a total of saline contents of 31.55 grammes per litre. The water in which the salts are dissolved is drawn from a natural spring at Harrogate. The constituents are well balanced in accordance with therapeutic requirements.

SPECIAL SCOTCH WHISKY.

(MESSRS. CHARLES TUCKEY AND CO., 3, MINCING-LANE,
LONDON, E.C.)

The analysis of this well-matured spirit was as follows: alcohol by volume, 46.59 per cent.; extractives, 0.28 per cent.; mineral matter, 0.01 per cent.; acidity reckoned as acetic acid, 0.02 per cent. The secondary products present in 100,000 parts of absolute alcohol were as follows: ethers, 49; aldehydes, 43; furfural, 3; and higher alcohols, 200. These results are in conformity with the statement as to the age of the spirit being 10 years. It is smooth to the palate and mild in flavour. Its colour is somewhat high due to storage in wood. It is well adapted for dietetic purposes owing to its purity and quality.

ADRENALIN SOLUTION.

(MESSRS. BURROUGHS, WELLCOME, AND CO., LIMITED, SNOW
HILL BUILDINGS, LONDON, E.C.)

Adrenalin is now an official preparation of the Pharmacopœia, and it is satisfactory that this important product is being manufactured in this country. The "Wellcome" brand solution of adrenalin B.P. conforms to the requirements of the Pharmacopœia and in addition it is physiologically standardised. Each bottle contains 10 c.c. of a 1 per 1000 solution of the crystalline active principle of the suprarenal gland.

LYSOL.

(MESSRS. EVANS, GADD, AND CO., 100, FORE-STREET, EXETER.)

A chemical examination of this fluid soon disclosed the use of high quality materials. On removing the soap by means of caustic soda and calcium chloride a practically colourless filtrate was obtained containing the tar acid. On acidifying this filtrate the tar acids were liberated, and they were of a pale brown colour. In many similar preparations we have examined the phenols employed are generally quite dark in colour. The separated tar acids measured exactly one-half the volume of the lysol. The preparation is limpid and mixes with all proportions of water to a clear bright fluid. It is detergent as well as powerfully antiseptic.

VEGETABLE AND MEAT EXTRACT.

(MESSRS. GEORGE MASON AND CO., CHELSEA WORKS, WALHAM
GREEN, LONDON, S.W.)

This preparation has all the appearance and consistence of a meat extract, but it is composed chiefly of soluble vegetable materials. Moreover, it has the pleasant attractive flavour of meat extract and similar appetising qualities. It contains, however, nearly half its weight of salt. Analysis gave the following results: moisture, 13.70 per cent.; mineral matter, 50.00 per cent., containing 48.10 per cent. sodium chloride; total nitrogen, 3.84 per cent.; proteins precipitated by bromine, 2.05 per cent.; other nitrogenous matters, 19.55 per cent.; extractives soluble in alcohol, 12.70 per cent. The preparation affords a stimulating "tea" and as an adjunct fills a useful place in the sick dietary.

SPARKLING MUSCATEL (GOLDEN GUINEA).

(MESSRS. H. N. GILBEY AND CO., 15, CHARLOTTE-STREET,
FITZROY-SQUARE, LONDON, W.)

This is a pleasing French sparkling wine with the well-known muscatel flavour. On analysis the following results were obtained: alcohol by volume, 11.17 per cent.; extractives, 5.42 per cent.; sugar, 3.57 per cent.; mineral matter, 0.17 per cent.; volatile acidity reckoned as acetic acid, 0.14 per cent.; and fixed acidity calculated as tartaric acid, 0.88 per cent. The wine may be described as moderately dry; it has an agreeable delicate flavour, and for some purposes may well replace the more expensive champagne.

A VETERAN PRACTITIONER.—Mr. Daniel Carmichael, F.R.C.S. Edin., L.R.C.P. Edin., one of the oldest medical practitioners in Gosforth, Newcastle-on-Tyne, has recently died. He qualified in 1859, and was the first medical officer of health appointed by the Bedlington Council.

ZYMOTIC DISEASES IN BELFAST.—At a meeting of the city corporation of Belfast, held on March 1st, it was stated that between Jan. 17th and Feb. 13th—the period under review—184 cases of scarlet fever, 4 of enteric fever, 1 of simple continued fever, 1 of puerperal fever, 15 of diphtheria, 1 of membranous croup, and 18 of erysipelas had been notified. The death-rate from all causes was 22.6, that from zymotic diseases 1.7, and that from chest diseases 8.6 per 1000. There were 224 cases of infectious diseases notified. Reference was made at the meeting to a report of Dr. A. G. Robb on Purdysburn Fever Hospital, in which he showed that, with the exception of the fever hospital in Sheffield, there was not a hospital in the three kingdoms where the average cost of maintenance was as low as at Purdysburn. Return cases of scarlet fever at Purdysburn were very much lower than the average of return cases in other fever hospitals. Cross infection was due to patients being admitted with one disease who were at the same time in the incubation stage of some other disease.

THE LANCET.

LONDON: SATURDAY, MARCH 20, 1915.

A Plea for Consideration.

THE public at large, whose opinion is expressed at least as much as it is guided by the daily journals, is beginning to recognise that the medical profession has a very severe strain placed upon it by the conditions of war, and to perceive that some consideration may justly be claimed by its members when shortage of numbers prevents them from dealing satisfactorily with temporary or local over-pressure of work. In a letter to the local press of Newcastle, Mr. D. RANKEN has put the case with great clearness in terms applicable to many other localities. Elsewhere, as well as at Newcastle, the ranks of the local medical profession have been depleted by the call which civilian practitioners have obeyed to serve their country in the navy or army; local increase or diminution of working population has taken place owing to the presence or absence of works for the manufacture of war material; and in hundreds of thousands men have gone to join the colours, leaving their families behind them. In these circumstances the medical men who are left are working under new conditions, and have to get their work done somehow, or be blamed for neglect, although, as we must point out, many of those still in civil practice have had to remember increasing years and growing unfitness for strenuous exertion, or they would not have remained where they are. In the letter referred to Mr. RANKEN makes practical suggestions. He asks the public to call as seldom as possible upon medical men at untimely hours, to make their requests for visits before the medical man has started on his daily round, and to avoid calling him out at night and on Sundays except in cases of extreme urgency. These very simple demands upon the forbearance of patients and their friends are endorsed by the *Newcastle Journal* in a sympathetic editorial article, which treats them as entirely reasonable, and points out that they affect "not only the interests of the hard-worked doctors but the best interests of the civil population as well." It is in this spirit that we hope to see a difficult and trying state of affairs met during the months that now lie before us, when the pressure of work is likely to increase rather than to diminish, while the number of hands available to deal with it will not be augmented in any adequate degree.

The extent of the dislocation of medical practice throughout the country and the various ways in which that dislocation shows itself can readily be appreciated by those who have read the various

articles by our Special Commissioner upon local conditions of practice. War has suddenly created, practically throughout Europe and beyond its borders, a demand for the services of the surgeon and physician wholly without parallel in history, and it is not alone in the supply of munitions of war to her allies that our country is drawing upon her resources beyond what is necessary for her own immediate needs. But the change thus wrought with startling suddenness has not been confined to the diminution of the number of practitioners serving the civil population. A simple general increase of work would have been an easier matter to cope with than the changes of various kinds best perhaps described by the word dislocation. In its most general aspect the war has greatly impoverished in many places large sections of the population among which the local practitioners have been in the habit of finding their most paying patients; on the other hand, there are sections of the population in the same localities or in others which have become more prosperous than they were under normal peace conditions. This, however, does not necessarily mean that the loss and gain to the medical man balance one another. Many of those who have profited are unlikely to admit having done so, and the generous willingness of the civil practitioner to attend the dependents of men serving with the colours, where these are in necessitous circumstances, has in many cases involved them in giving free treatment to women and children who are better off than when the head of the family was at home. Again, demand is made for free medical treatment of the troops in towns where these are billeted upon the townsfolk without due provision being made for their liability to sickness. These sudden influxes of population, whether in the form of military units or of additions to the working-class population, imply a diminished number of inhabitants in other localities and a corresponding loss to former medical practitioners, while not as a rule benefiting the medical men in the new localities.

The conditions affecting the medical profession, of which the above may be taken as examples, are, as has been pointed out, conditions of dislocation, of temporary derangement, and of inconvenience. The public is affected and is no less interested than the medical profession in procuring the smoothest possible working for the machinery by which its health is protected, and recourse must be had everywhere to patience, mutual forbearance, and that readiness to give and take which makes matters go smoothly where men and women have to combine in circumstances of difficulty and stress. That such mutual forbearance as we have indicated will be evinced we feel confident, and we express the hope that the need for it will make an impression upon the public mind which will remain when war is over and peace once more restored. The difficulties which may arise will

generally be due to a "shortage" of medical practitioners. We invite the public to remember that shortage, and to consider the causes out of which it has arisen. It has shown itself recently in an inadequate supply of medical men to fill the minor appointments constantly offered to the junior members of the profession. The supply was found to have become inadequate when the Insurance Act promised in some industrial districts better prospects in private practice than had prevailed before, and the demands made by the war have accentuated the deficiency.

Epidemic Cerebro-spinal Meningitis.

THE special debate on the epidemiology of cerebro-spinal meningitis, which took place on Feb. 26th and March 5th in the Section of Epidemiology and State Medicine of the Royal Society of Medicine, proved of the greatest topical interest, for discussion among those who are able to speak with some authority on this subject should allay growing apprehension on the part of the public, while stimulating scientific interest, if such stimulus was needed, in the problems presented by one of the most remarkable of our epidemic visitations. And the problems are many. The extent to which cerebro-spinal meningitis has prevailed among us in the past is really not certain, and it is probable that many outbreaks have gone undiagnosed in various parts of the world, even since our pathology has recognised the disease as an entity. We know that there have been severe epidemics in France, Germany, Italy, and some parts of the United Kingdom in recent times, but whereas the disease was identified more than 100 years ago, it is only in the present century that any close scientific study of it has been forthcoming on the basis of the systematic search for the meningococcus, now recognised as the invariable concomitant, if not the principal causative agent of the disease. The result has possibly been to produce an impression of increasing public danger from this source which would not be warranted by the facts, if they were clear to us. The threat which any dangerous infection may offer to our soldiers aggregated in camps necessarily increases such an impression, and it is well known that during the last four months there have been outbreaks in several home camps; and camps, however hygienically contrived and scientifically run, must sometimes present, particularly in bad weather, conditions favouring the spread of any infection. Were it not for this fact the enormous amount of care which is expended over medical organisation would be wasted, for, apart from the special risks of concentration, a camp, it must be remembered, is a healthy community consisting, for the most part, of selected men in the prime of life, discharging arduous duties, but freed alike from any of the perils of the crowded town and relieved from the day to day anxiety of pecuniary struggle.

Infectious disease in camps loses a part of its grave dangers because of the favoured personnel, but apart from the purely military point of view there always remains the circumstance that an epidemic, even if its morbidity be slight, deprives the army of valuable material, while such a disease as cerebro-spinal meningitis, where the mortality is high, is a particular source of anxiety. From the debate at the Royal Society of Medicine a great deal of interesting information was obtained, all, however, pointing to a certain obscurity in the pathology and in the methods of spread, and all emphasising the difficulty of diagnosis, making it necessary that those in charge of the health of closely packed communities must be especially on their guard against insidious and possibly unsuspected danger. Cerebro-spinal meningitis is ordinarily a disease of sporadic occurrence in this country, scattered widely over the population, though exceptionally occurring in groups. Even in definite epidemics, such as that which affected Glasgow in 1907, it has seldom seemed to be directly infectious from case to case in the way in which measles or scarlet fever, for example, is infectious. Dr. A. K. CHALMERS pointed out, however, that the incidence in Glasgow was greater in the parts of the town which were most crowded and had the highest mortality from all causes. Several speakers adopted the view that in regard to its infectivity and prevalence the meningococcus was more closely allied to the diphtheria bacillus or even to the pneumococcus than to the organisms producing acute catarrhal infections. Sir WILLIAM OSLER, in reviewing the epidemiological features of the disease, alluded to its usual low rate of morbidity, and emphasised the important part played by the carrier in the spread of this disease, and also discussed the variability of the meningococcus intracellularis meningitidis. Since the discovery of this organism by WEICHSELBAUM in 1887 subsequent researches have confirmed the view that it is the cause of the disease; but serological studies and the differing results of treatment by specific serums all tend to show that various strains of this organism exist, to one of which the name of parameningococcus has been applied. Dr. J. C. G. LEDINGHAM, whose remarks we published in full last week, briefly reviewed some of the chief cultural and serological characters of the meningococcus. He pointed out that in regard to the identification of the organism from the throats of carriers the criteria employed have not always been of uniformly strict character, and that this fact may account for the variation in recorded statistics. It seems, however, to be quite clear that the carrier plays a very important part in the development and spread of the disease, and it is to be hoped that the present epidemic may result in some increase in our knowledge of this problem of the carrier and in the evolution of means for dealing with it satisfactorily. Certain statistics appear to show that in most

cases of convalescents from the disease the meningococci can no longer be found in the naso-pharynx after three weeks, but it is also probable that a few cases of chronic carriage of the organism occur. It is, however, not the convalescent carriers, but the healthy carriers who seem to play the most important part in the spread of the disease, since they are not detected unless systematically looked for, and they are sometimes very numerous, far exceeding the number of cases of the disease. In other words, each case of the disease may be the origin of a large number of healthy carriers who may serve to spread the disease widely and may be the means by which fresh outbreaks of the disease originate. Dr. LEDINGHAM even suggested that the chronic carrier with a zone of carriers around him may act as the connexion between one epidemic and the next.

Dr. J. A. ARKWRIGHT brought forward evidence against the view that meningitis as such was spread from one patient to another, mentioning that in one epidemic where nearly 2000 houses were implicated, under 7 per cent. of the houses furnished more than one case of the disease. Such an observation clearly supports the hypothesis of carriage of the germ by subjects themselves unaffected by its presence. When the organism is transported for long distances it can be disseminated in any of the usual manners which close contact suggests. The speakers were not in agreement as to the extent of the present prevalence. Professor JOHN ROBERTSON, medical officer of health of Birmingham, thought we were now in the presence of a widespread epidemic, and pointed out that where soldiers were billeted in poor quarters they ran more risk. The War Office has already acknowledged the justice of this view, and Mr. H. J. TENNANT, in the House of Commons on Monday last, stated that special instructions had been issued to all commands to ensure that the troops are not overcrowded in insanitary dwellings. Dr. W. H. HAMER, medical officer to the London County Council, doubted whether the increase of deaths from cerebro-spinal fever had been very great, obviously alluding to the difficulties of diagnosis. He showed that the increase of cases of cerebro-spinal meningitis corresponded with an increase of deaths from bronchitis, pneumonia, and influenza, suggesting that the prevalence of acute catarrhal conditions was an important causative factor. Other aspects of the disease were considered by various speakers with a view to giving some general guidance as to the duration of the incubation period, the diagnosis, and the treatment. Dr. W. D'ESTE EMERY made the interesting observation that the discrimination between the meningococcus and the gonococcus was often a matter of some importance, since gonococcal meningitis did occur, though rarely. He thought, however, that mixed or secondary infections of the meninges were very unusual. This observer thought that

the death-rate had been exaggerated owing to mild and non-fatal cases being missed, pointing out that where systematic lumbar punctures were done in children's hospitals cases of meningitis were found not infrequently which ran a mild course, and which in the absence of modern methods of diagnosis would have been regarded as rheumatism or bronchitis.

It is probable that systematic study of the results of treatment in the present outbreak will produce an advance in our knowledge of the effects of serums. Some excellent results are on record from the use of Flexner's serum, while in other instances it has not proved effective. The results of the use of polyvalent serums, and of other serums prepared in this country, will be awaited with great interest and should throw further light upon the bacteriology and epidemiology of the disease. A satisfactory solution of the carrier problem has yet to be reached, but here again we may expect that valuable experience will be gained if records are kept and subsequently published. It is well to emphasise that the precautions which are being taken with the troops have been very carefully thought out by the Army Medical Department with a view to cutting infection short in the most rapid manner. The degree to which this is possible in civil life is doubtful, but under military conditions the problem is more under control. All cases of unaccountable headache, of apparent ptomaine poisoning, and of vomiting, with or without rise of temperature or pulse, as well as all cerebral cases, are isolated and notified. When the patient is diagnosed to be suffering from epidemic cerebro-spinal meningitis he is immediately sent to the isolation hospital, and not only his bedding but that of all his immediate neighbours is destroyed, and their blankets and clothing sent for disinfection. All the men sharing his room or hut are isolated from the first and kept under special observation for signs of the disease, swabs being taken from them by an officer deputed for the purpose. Not until these swabs prove to be negative is the house or hut pronounced free from infection, until when no man in it is allowed to return to duty. The isolation is real, for the men are drilled and paraded apart from the rest of their unit, and no direct inter-communication is allowed between them and the cookhouse, while all feeding utensils are swilled out with boiling water, and every man uses his own cups and plates. All waste matter is immediately destroyed by fire, special latrine arrangements are made for the use of contacts, and the systematic destruction of lice and fleas is undertaken, while samples of vermin are collected alive for investigation. Further, there is provision made for the isolation of carriers, through whose instrumentality, it seems certain, some of the outbreaks have arisen. The energetic action of the medical department is much to be commended, and forms one of the proofs that the eulogy recently pronounced upon the department by Lord KITCHENER was well deserved.

Annotations.

"Ne quid nimis."

"BACK TO LISTER."

UNDER this heading, which as he informed his audience was suggested to him by Sir James Crichton-Browne, Sir Rickman Godlee delivered a bright and timely discourse at the Royal Institution on Friday in last week. He made no attempt to trace the various steps by which Lister was led to his conclusions about the cause of suppuration, and refused to harrow the feelings of an audience, which was of course only partly medical in composition, with the usual lurid pictures of hospital conditions before the introduction of the antiseptic system. He began the great story of the growth and development of modern surgery at the point where Lister, a highly equipped man of science and a linguist, as well as a most observant and successful clinician, perceived that in Pasteur's discoveries the solution should lie of some of the terrible problems which then beset hospital surgery. It was a commonly accepted deduction, drawn by noting the difference in the behaviour of fractures with unbroken skin from that of compound fractures, that the air had a morbid influence. The discoveries of Pasteur showed that: 1. Putrefaction is a species of fermentation. 2. It is caused by the growth of micro-organisms and does not occur independently of them. 3. The micro-organisms that produce fermentation and putrefaction are conveyed by the air on the dust that floats in it. 4. These micro-organisms can be destroyed by heat and other agencies or separated by filtration. 5. Certain recognisable organisms produce definite and distinct fermentative processes. 6. All of these organisms require oxygen. Some of them flourish in the presence of free oxygen (aerobic), others only in its absence (anaerobic). The latter acquire their oxygen from the bodies which, by their growth, they are causing to ferment or putrefy. 7. Many natural animal and vegetable products have no tendency to ferment or putrefy even in the presence of oxygen if collected with proper precautions and kept in sterilised vessels. 8. Spontaneous generation has never been observed to occur. Pasteur's work, said Sir Rickman Godlee in thus summarising its teaching, presented Lister with two great fundamental facts: (1) That putrefaction is caused by germs which can be destroyed by heat and chemicals, and separated by filtration; (2) that germs are carried by the dust in the air, and in 1865 the problem seemed to be to kill the germs which might have gained access to the wound before it came under treatment, and to prevent the air from carrying in others afterwards. Lister first applied what he called the antiseptic principle to compound fractures, the cases of which were particularly liable to be followed by the hospital plagues of pyæmia, erysipelas, and hospital gangrene. In the early stage of his work he used a very strong antiseptic and did his best absolutely to exclude the air, and his results were strikingly good, said Sir Rickman Godlee, in spite of the fact that the undiluted acid did actually cause a certain amount of superficial sloughing or death of the tissues. He then explained to his hearers how, as time went on, Lister introduced the spray in order to deal more effectually with the air, and reviewed the circumstances which led to the adoption of

the procedure, and later to its abandonment, this part of the lecture being particularly valuable for delivery to a lay audience, as those few people who are still foolish enough to disbelieve in the discoveries of Lister usually state that he changed his methods of treatment so much that he could not be a trustworthy guide. As a matter of fact, Lister never changed his grand objects or his main methods, although he modified his technique as it became obvious that the air was a minor danger compared to the germs on the skin of the patient, the dirt on the hands of the surgeon, the unpurified sponge, or the badly cleaned instrument. Gradually he lessened the strength of his antiseptic solutions, being willing more and more to credit the normal tissues with the power of resisting invasion, and at this point in the story of Lister's work Sir Rickman Godlee dealt with the suggestion that there is a fundamental antagonism between the aseptic and antiseptic treatment. He found that the comparison between the two, which is so often made, is misleading, because most of the advocates of aseptic surgery use chemical antiseptics for one purpose or another, while all employ heat, a most powerful antiseptic, with freedom. The great difference between the aseptic and the antiseptic surgeon is that the former requires an amount of paraphernalia to carry out his procedures which puts them almost beyond the reach of any except hospital surgeons, and quite beyond that of surgeons with a fighting army. Sir Rickman Godlee read to his audience a letter from Sir Anthony Bowlby describing the conditions prevailing at the front, which sufficiently showed that aseptic practice would be too often useless. "In this trench warfare," said Sir Anthony Bowlby, "you must remember that, if a man is hit, he often falls into filthy mud and water, which may be three feet deep or more. Remember also that the trench is only 2½ feet wide. *If it is night*, you can only grope about in the dark and can do no dressing of any kind, for you can't even get any clothes off in the dark, and in so cramped a space, and you must try to get the man away to a 'dressing station' half a mile distant, and thence to a field ambulance. *If it is daylight*, you can't get the man out of the trench at all, and he may have to be kept there for many hours, because he would certainly be killed if he was got out of the trench. And the water in the trenches is hopelessly polluted and soaks his clothes and his wound. It is only too evident that large lacerated wounds, and especially bad bone smashes, are so contaminated that it can never be possible to render them aseptic." There is clearly not much room for strict aseptic surgery at the front, and Sir Rickman Godlee closed his interesting address by saying pithily, "The only way to stop sepsis in war is to stop war altogether."

THE FREEZING POINT OF WATERED MILK.

Dr. G. W. Monier-Williams has undertaken for the Local Government Board an investigation into the freezing points of a considerable number of milks known to be of natural unaltered composition, with the object of ascertaining whether the freezing point is capable of being used with any advantage in guarding the quality of the milk-supply, and whether the indications afforded by it are more accurate than those obtained by the well-known chemical methods of examining milk already in use. His conclusions appear in a report issued by the Local Government Board this week. He

found that the average freezing point of 141 samples of genuine milk was -0.5345°C ., the values ranging from -0.558°C . to -0.514°C . The freezing point, he observes, appears to be the most constant of any of the properties exhibited by genuine milk. Although unaffected by the removal of fat from or the addition of separated milk to genuine milk, the freezing point is raised by the addition of water to the milk. The determination of the freezing point may thus, in certain circumstances, be applied with advantage, as a confirmatory test, to the detection of added water and to the approximate estimation of the amount present. It is concluded, however, that owing to the experimental difficulties involved in obtaining reliable results it is somewhat doubtful whether the method is capable of general application for purposes of milk-control. The report presents, we think, for the first time the results of a detailed investigation made in this country on the freezing point of milk and its practical utility, but Dr. Monier-Williams states that this process has been used for some years in several continental laboratories.

FABISM.

In some parts of Sardinia cases not infrequently occur of acute febrile anæmia with jaundice and hæmoglobinuria, and are popularly supposed to be due to the eating of raw fresh beans, possibly also of cooked beans, a further attribution being to inhalation of the blossoms of the bean plant. The clinical picture presented by these cases is very characteristic and a rapidly fatal termination is far from uncommon. Dr. A. Gasbarrini in a recent issue of *Malaria e Malattie dei Paesi Caldi* gives details of 10 cases, and draws attention to the similarity of the symptoms with those of "icterohæmoglobinuric fever" described by Plehn. In a typical case there are rigors followed by high fever, vomiting and sense of oppression, marked anæmia, bloody urine, and distinct jaundice, which increases up to the third day. After this date in mild cases the fever and hæmoglobinuria disappear, a trace of albumin perhaps remains in the urine, the jaundice diminishes, and recovery takes place in about a week. In severe cases the fever is greater, profound and progressive hæmolytic supervenes, and death takes place on the fourth or fifth day. Dr. Gasbarrini, having established the fact that in none of his cases was there any evidence of malaria, as shown by the absence of plasmodia and a negative result with the Bordet-Gengou test carried out with malarial antigen, performed some experiments with a view to trace any connexion between the disease and the ingestion of beans, for these had been consumed in all his cases immediately prior to the onset of symptoms. An attempt to reproduce the morbid features of the disease in a convalescent patient by administering some of the fresh raw beans which had caused the death of a child failed completely. The same result happened in animals. On the other hand, in a rabbit the intravenous injection of serum obtained from one of the patients produced hæmoglobinuria, rapid deglobulisation, and leucocytosis, while in another rabbit the serum of a recovered patient was without any effect. This result is certainly interesting and deserving of further investigation. The results of these experiments do not, the observer admits, permit him to draw any conclusions as to the etiology and pathology of fabism. He uses this

appellation for convenience of description, but does not consider it justifiable for the moment to refer the disease to the ingestion of beans or to the inhalation of the perfume of the flowers—he does not even attempt to constitute fabism as a special morbid entity. —

DANGER OF THE CHOLERA CARRIER.

THE presence of cholera vibrios has been reported in the Calcutta water-supply underground reservoirs, and measures were at once taken to chlorinate the water. The matter was then further investigated, and on Feb. 13th, according to the Proceedings of the Calcutta Municipal General Committee, the bacteriological authorities again succeeded in isolating a true cholera virus from the samples supplied to them. The matter was serious, but as no explosive outbreak of cholera had taken place in Calcutta it seemed to the authorities that there might possibly be some mistake. Investigation showed that the samples had all been collected by a bearer who had long been in the employ of the bacteriological laboratory. This man had had an attack of cholera some years ago, but had not been a day off duty of late. There had also, as far as could be ascertained, been no case of cholera in his family. On the bearer being subjected, however, to close personal examination Major E. D. W. Greig, I.M.S., discovered that he was a regular cholera carrier. The investigation is not yet complete, but the health officer is inclined to think that the key to the mystery has been found. In his report on the case he adds that this bearer has not been permitted to take any more samples of water and has been excluded from the bacteriological laboratory, and all samples of water are now being collected by the assistant analyst and by the medical officer, Pulita. In future no samples will ordinarily be taken from Tallah, as it is undesirable to have a reservoir opened needlessly. Major Greig well deserved the thanks which he has received for his invaluable assistance in elucidating a difficult bacteriological problem. This case affords an instance of the constant watchfulness and extraordinary care necessary in public bacteriological work. —

THE SENSATIONS OF THE ALIMENTARY CANAL.

The *American Journal of Psychology* for January contains a paper by Mr. Edward G. Boring in which are recorded the results of a long series of experiments on himself and others bearing on the difficult question of the sensibility of the alimentary canal. Various methods were devised to elucidate the subject. Thermal, chemical, and electrical stimuli were applied to the œsophagus, stomach, rectum, and colon, and among the important findings obtained in this way reference may be made to the following. The œsophagus is sensitive to warm and to cold stimulation throughout its whole length. Extremes of heat and cold cause pain. The sensations of temperature originating in the œsophagus are often referred to the throat, while the pain sensations are sometimes localised in the head. Distension of the œsophagus by mechanical stimulation results in a pressure-pain sensation resembling that obtained by suitable methods (algometer) from skeletal muscles. Chemically it is sensitive to alcohol and hydrochloric acid, but not to oil of peppermint or mustard or pepper in suspension. As a rule, the reference of sensations arising in the œsophagus is either to the throat or

to the region below the sternum, and never to any point more than 1 centimetre from the mid-line. Mr. Boring is inclined to believe that this tendency to localise œsophageal sensations upon soft portions of the body suggests that these portions come by virtue of their mobility to be connected in experience with internal parts. It is at least as likely, however, that this reference to the throat and area below the sternum is *via* the segments of the cord from which pass the sensory stimuli from the œsophagus. In the case of the stomach, cold and warm stimuli produce the corresponding sensations, identical in quality with cutaneous cold and warmth. Extreme warmth gives rise to pain. Distension causes a sensation of pressure pain. Electrical stimulation produces the characteristic sensations. In all these instances it is difficult to exclude the participation of superficial tissues, particularly in the case of electrical stimulation. The rectum is probably insensitive both to warmth and cold; water at 60° C., however, evokes a sensation of pain. Distension of the rectum so inevitably arouses the call to defæcation that any specifically local sensations of pressure are masked. With increasing distension pressure pains in the abdomen and genitalia are set up. Both alcohol and hydrochloric acid give rise to sensations when brought in contact with the rectal mucosa, while oil of peppermint, pepper, and mustard do not. Hot and cold enemata do not produce thermal sensations in the colon; any sensation they produce is always one of pain. Distension of the colon causes pressure pain which cannot be attributed to the intestine itself.

DEW-PONDS OR MIST-PONDS.

THE permanency of the volume of water contained in the ponds on the high level of the downs compared with the failing supplies of the adjacent low-level hollows has long been an interesting topic for lay and scientific speculation. We have hoped always for some improbable or fantastic explanation of these interesting reservoirs, but it would appear from the researches of Mr. Edward A. Martin, F.G.S., on the subject that while it is true that a special condensation process is accountable for the maintenance of the dew-pond, yet this has its origin neither in peculiar differences of electric potential nor to any remarkable property of insulation possessed by the bed of the pond.¹ It is known that the source of the water is, at all events, not a geological one, and that the supply is derived from condensation from super-saturated air, but why the dew-pond should be a concentration point has not so far received a complete explanation. Some 14 years ago the formation of these ponds was under discussion, when the favourite view was that a difference of electric potential caused an attraction between the particles of moisture and the summit of the hill upon which the pond is situated. A simple experiment appeared to confirm this idea, for when two similar receptacles were placed in the neighbourhood of a dew-pond it was reported that there was a marked increase in the water connected to the earth by means of a conductor, while in the insulated basin the quantity collected was decidedly less. However, this explanation no longer holds good, for Mr. Martin appears to have established that the water of these elevated ponds is maintained by the peculiar condensation of mists over the surface of

the pond blown in from the sea, the term dew-pond being a misnomer, for which mist-pond should be substituted. Next to rain the chief sources of supply for the ponds are mist and fog, especially as regards those ponds which are at the very summit of the hills, where the condensation resulting from the altitude is greatest. Then it would appear that the quantity of sodium chloride in the ponds is large, and the particles of salt in the mist accelerate its precipitation and condensation. The downland fog, in other words, makes good the unequal relations existing between rainfall and evaporation in the summer months, and so the "dew-ponds" remain while the ponds in the valley dry up. The hint is plain to the stock farmer.

CHAULMOOGRA OIL IN THE TREATMENT OF LEPROSY.

Chaulmoogra oil for a number of years has been used in the treatment of leprosy with a certain amount of success, and cases showing improvement under this treatment have been recorded in our columns from time to time. In some cases, however, its continued administration by the mouth has been rendered impossible owing to the nausea and other disturbances of the system arising from its employment. Various other methods of using it have been tried, and among them hypodermic injections of the oil in combination with camphor and resorcin. Not long ago Dr. V. Heiser, Director of Health for the Philippine Islands, published accounts of apparent cure in four instances in which these injections of the oil had been used,¹ and in a special supplement to a recent number of the *United States Public Health Reports* he furnishes details, with numerous illustrations, of 9 more cases in which this method of treatment had been employed over a period of two years. Originally 12 cases began the injections together, but after a year three of the patients, though all of them had shown some evidence of improvement, declined to go on with the treatment. Dr. Heiser therefore confines his results to the remaining nine cases. One was apparently cured and was classed as "microscopically negative" as regards leprosy. In four others the disease had been arrested and had practically disappeared, three more had improved markedly, and in one the improvement was only slight. Thus all nine patients had been benefited by the treatment to a greater or less extent. The injections were given at weekly intervals in ascending doses, beginning with 1 c.c. As the toleration of the injections varies in different individuals, the dose must be regulated to prevent reactions of too violent a nature. At the same time hot baths, with 2 per cent. of sodium bicarbonate, were given, and it was found that those who took the baths regularly improved more quickly than those who did not take them. Dr. Heiser claims that this mode of treating leprosy gives more consistently favourable results than any other method that has hitherto come under his notice. It is, he says, equally efficacious in all forms of the disease. As the results reported seem to be very encouraging we should like to see the treatment tried on a more extensive scale, and we hope that other experts in affected areas will therefore give a fair trial to the hypodermic injection of chaulmoogra oil in combination with camphor and resorcin.

THE TREATING OF SOLDIERS.

In the coroner's court at Eastbourne recently an inquest was held upon the body of a young soldier who had been handed over to the guard of his battalion at night by the police as "dead drunk." He had then been left by the guard to "sleep it off," and had been found dead in the morning. Evidence showed that the deceased, having already had more beer than was good for him, had asked some fishermen who had a bottle of whisky in their possession to allow him to drink from it, and that this had been followed by some sort of wager that he would finish the contents. Post-mortem examination revealed signs of recent acute alcoholism, and no signs of chronic alcoholism were present. A verdict of "Death from misadventure" was returned, comment being made by the coroner upon the cruel thoughtlessness shown by those treating soldiers, a course almost certain to bring the men into trouble. The suggestion was also made in the course of the case that men brought insensible to a guard-room should be seen by a medical man, whether believed to be drunk or not.

MIKULICZ'S DISEASE.

Mikulicz's disease may be described as a condition of bilateral chronic swelling of the lacrymal and salivary glands in an otherwise apparently healthy subject; it was first described in 1888. There are certain special features about these cases: the parotid glands especially are nearly always swollen—they are painless, smooth, and firm; often similar swelling involves also the submaxillary and sublingual glands. The lacrymal glands enlarge early. The liver and spleen are not increased in size. After a time the glands may subside and nothing more may happen. Such is an ordinary case. But many instances have now been reported, an interesting review of which is given by Dr. Thursfield in the *Quarterly Journal of Medicine* (1914, vol. vii., p. 237), in which there are definite blood changes as well. This at once opens up the question as to whether Mikulicz's disease can be allied to lymphatic leukaemia. But the blood whilst showing a marked relative excess of lymphocytes presents no total increase of leucocytes; there may be, in fact, a leucopenia; the spleen, too, is not usually enlarged, nor is there the general glandular hyperplasia frequently found in lymphatic leukaemia. In spite of these differences, however, the similarity in course of the disease—some of the Mikulicz's cases ending fatally, as do cases of lymphatic leukaemia—and the resemblances in the pathological findings in the two conditions when the blood is changed in character, make it probable that certain of the cases of so-called Mikulicz's disease are in reality closely allied to the true leukaemias. Certain cases presenting this peculiar distribution of glandular swellings may be due to other causes, such as tuberculosis, gout, and syphilis. For the rest no definite cause can yet be assigned. Mikulicz's disease must, in short, be regarded more as a syndrome presenting grouped symptoms but which owns widely varying causes.

Professor Henry Roy Dean, M.D., F.R.C.P., whose research work as professor of pathology at the University of Sheffield received Government recognition in a subsidy for its continuance, has been appointed professor of pathology and pathological anatomy at the University of Manchester.

THE FALLING BIRTH-RATE IN GERMANY.

(FROM A CORRESPONDENT.)

AT a meeting of the Deutscher Verein für Öffentliche Gesundheitspflege a paper was read recently by Herr M. von Gruber on the dangers threatening the German nation on account of the steady decline in the birth-rate. The lecturer discussed his subject from many points of view, illustrating his arguments with numerous statistics and tables. Without such aids, however, his message is perfectly clear. He says:—

Rapid Fall of Birth-rate in Germany.

It is common knowledge that the birth-rate in France has fallen much, but it is not generally realised how rapid and great has been the fall in the birth-rate in Germany during the last decades. This fall is shown in the following table, which refers to the number of marriages, births, and deaths for every 10,000 inhabitants at various dates since 1870:—

Year.	Number of marriages.	Births.	Deaths.
1870	77	401	290
1880	75	391	275
1890	80	370	256
1900	85	368	232
1905	81	340	208
1910	77	307	171
1911	78	295	182

This shows that though the number of marriages has practically not changed, the birth-rate has fallen by more than 25 per cent., and the mortality by 35 to 40 per cent., which fact accounts for the increase in the nation's surplus population. The fall in the birth-rate is, curiously enough, greatest in the hitherto so prolific Saxony, where it is more than 40 per cent. The fall is greatest in the towns and centres of industry, but it is also evident in the country districts, particularly in the neighbourhood of large towns. As a rule, the fall is greater and more rapid among Protestants than among Catholics, and it is greatest in communities which elect Social Democratic representatives. The fall is most striking in Berlin, where the birth-rate has diminished by a third within the last 30 years. Here the birth-rate is highest in the working-class districts, but even in these the fall is noticeable. It is beyond dispute that the lower classes in town and country have followed the example of the upper classes in the limitation of offspring. Berlin can no longer maintain its numbers by its own birth-rate: thus in 1912, 1000 women, whose ages ranged from 15 to 45 years, gave birth to only 73 living children, and this figure would have to be raised to 113 if the population of Berlin were to be kept up to its present level.

Alcoholism and Venereal Disease.—The Limited Family.

The fall in the birth-rate is largely due to alcoholism and venereal disease, both of which are on the increase. Venereal disease in particular is to blame. In 1910 it was estimated that in a very large sick-club in Berlin 4.9 per cent. of the women and nearly 9 per cent. of the men suffered from venereal disease. Lenz has even calculated that 90 per cent. of the men in Berlin have at some time been infected with syphilis. What, however, is most important is the dependence of the decline of the birth-rate on systematic prevention of conception. A table dealing with the fall of the birth-rate in Berlin shows that this fall applies particularly to the birth of children in families already possessing a child or two. In other words, the third and fourth child, not to mention later children, are becoming more and more scarce. In spite of all this, in the period 1901 to 1905 Germany had produced a surplus population representing 14.8 to the thousand. At this rate the population in 1950 should be about 118 millions, and at the end of this century 250 millions.

At this point von Gruber naively remarked that such a population need not be a source of alarm. "The others would have to make place for us!" He admitted, however, that this optimistic calculation did not take into account the fall in the birth-rate. He continued:—

The productive capacity of the German Empire will, at the end of this century, be lower than it is in France to-day. When

once Germany adopts the two-child system the methodical temperament of the nation will ensure its uniform practice and inevitable consequences. Particularly ominous is the low productivity of the most gifted. Cross breeding among the mentally well endowed is of great importance in the evolution of intellectual qualities, as is well illustrated by the Imperial House of Hohenzollern. Nothing is more important for the existence and welfare of a nation than a sufficient supply of gifted leaders; without such the mass of the people is helpless.

The causes leading to the voluntary limitation of the family are many. Recent advances in science, improving the conditions of life and prolonging it, are all to the good of the individual rather than of the community. Indeed, these interests are apt to clash, and owing to the present selfish individualism of man a course is often chosen which benefits the present generation at the cost of succeeding generations. The family is no longer an institution for the reproduction of the race; and the child's work and support of the family are progressively reduced by laws insisting on hygienic and educational measures and the limitation of child labour. Owing to insurance against old age and disease parents no longer feel the necessity for creating an offspring which shall keep them in their old age. Lack of house accommodation in the towns, the employment of girls in shops and factories instead of in domestic duties render the successful rearing of large families difficult. It has become a popular belief that large families are detrimental to the health of mother and children, but this is not the case when, for example, a family of ten children has been born within the space of 20 years. This popular superstition is given the lie by statistics dealing with the birth-rate and the infant mortality in the various parts of Prussia. Westphalia, for example, has a birth-rate more than twice as great as that of Berlin, yet the former can boast of a much smaller infant mortality, and there is practically no difference in the expectation of life of the mothers in these two districts. The higher standard existing for child welfare and education is also partly to blame, for when the poor see what advantages accrue to this higher standard they try to attain to it by reducing their offspring, and hope by this reduction to raise their children in the social scale.

The so-called emancipation of woman is incompatible with the duties of a mother. She no longer devotes herself to the needs of a large flock of children; she performs her duties as a mother in a most perfunctory way, and aims at being her husband's companion rather than the mother of his children. Among the æsthetic it has become usual to regard childbirth as a brutal and nauseating episode, and the child as a blur on the artistic home and as a nuisance in clubs or on journeys. Among the most sterile are the Jews of Berlin. Their numbers have, indeed, increased between 1875 and 1910 by 102 per cent., but during this period their birth-rate has diminished by 11 per cent., and it has now fallen to 14 per 1000. In other districts the Jewish birth-rate has even fallen as low as 12.9 per 1000. This fall is traceable to the Jewish love of wealth and power, and it shows that dire need is not responsible for it, for on the average the Jews of Berlin are much richer than the Protestants and Catholics.

Proposed Measures, including Government Subsidies.

In relief of the existing position von Gruber made certain suggestions in the following tentative way:—

An estimate of the fate awaiting a nation which methodically adopts the two-child system shows that a population of a million with a yearly birth-rate of 19.8 to the thousand must after 15 years have dwindled to 918,400, after 50 years to 676,938, and after 100 years to 347,075. Ultimately the wealth of the individual would suffer. At present, according to Prussian statistics, the income per head of the population is 260 marks. According to the above hypothetical calculation of the decline of the population, the income per head would have risen after 15 years to 283 marks, but after 50 years it would have fallen to 269, and after 100 years to 265 marks. It is not sufficient to rely on reducing the infant mortality, for even if this were brought as low as 7 per cent., to which figure only New Zealand and Norway

have attained, the gain thus effected would be practically neutralised by a further fall in the birth-rate of 2 per 1000.

It is therefore imperative that a reform should aim at encouraging fertility and removing the advantages at present associated with sterility. The substitution of polygamy for monogamy, the emancipation of woman, and the State supervision of the child are inferior to the old family system economically and from the point of view of race-hygiene and culture. The maintenance and education of children in public institutions would be twice as expensive as the present family system. Were the family tie dissolved and loose connexions substituted, venereal diseases would spread, the standard of parentage would be lowered, and the frequency of sterility would be increased. It is an insufficient inducement to give birth to a child that its mother is permitted to visit it every Sunday in some State institution. The family ties must, therefore, be strengthened, and the attempt to place the married and unmarried mother on an equal footing must be checked. The present popular vogue of honouring the unmarried mother has little to do with compassion for her fate or a misplaced fervour for the preservation of the race; it is rather an insidious attempt to raise the social status of the unmarried mother and thus sweep away a hindrance to loose connexions.

For the sake of large families housing accommodation should be improved, garden cities should be built, and cultivation of the land should be encouraged. The community as a whole should contribute so largely to the rearing of children that it would be practically as cheap to have a large as a small family. These contributions should be available for every class, from the lower to the upper middle; for it is deplorable that the most virile class to which officers belong should find it difficult to raise large families. The standard of fertility should be so high that each couple would breed 3.75 children, which after the necessary reductions would be equivalent to about three children living to the age of 14 years. Were the Government to subsidise with 200 marks a year every child in excess of the first two, Germany, with a population of 66.3 millions, would have to pay 840 million marks a year. This sum could be raised by progressive taxation of the unmarried, of the childless, and of families with few children. Taxes on luxuries could also be raised for this purpose. It must be admitted, however, that an evil such as the two-child system cannot be eradicated by legislation.

The message of the paper was that the German mental attitude requires revision, and a campaign should be conducted against narrow intellectualism, the cult of money and luxury, and the widespread selfishness which sacrifices the good of the State for the good of the individual.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on March 11th, Sir WATSON CHEYNE, the President, being in the chair.

The Council offered their hearty congratulations to Sir George H. Makins and Sir Anthony A. Bowlby on being made Knights Commander of the Most Distinguished Order of St. Michael and St. George, in recognition of their services as consulting surgeons to the British Expeditionary Force in France.

Mr. John Murray was introduced, and having made a declaration in the terms of the oath prescribed by the Charter of 1800 was admitted a member of the Court of Examiners.

It was resolved to issue Diplomas in Dental Surgery to 20 successful candidates. It was also resolved that University College, Cork, should be added to the list of dental hospitals and schools recognised by the College.

A report was read from Mr. C. H. Golding-Bird of the proceedings of the Central Midwives Board during the past year. The best thanks of the Council were given to him for his services as the representative of the College on the Central Midwives Board. Mr. Golding-Bird was re-elected to this post for another year.

Sir FREDERIC EVE reported the delivery of the Hunterian Oration by the President, Sir Watson Cheyne, on Feb. 15th. The President was thanked for his oration, and he was requested to publish it.

The PRESIDENT reported that with reference to the letter addressed by him to the Home Secretary regarding the difficulty of obtaining subjects for dissection, he had received a note from the Home Secretary acknowledging the receipt of the letter and stating that it will receive his consideration.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The undermentioned has been granted a temporary commission as Surgeon in His Majesty's Fleet: Charles Denis Hanan.

The following appointments have been notified:—Staff-Surgeon: F. C. Robinson to the *Vivid*. Temporary Surgeons: H. Danvers to the *President*, additional, for Hospital Yacht *Queen Alexandra*; K. Wolferston to the *President*, additional, for Eastchurch Air Station; T. C. Blackwell to the *Victory*, additional, for R.N. Division, Blandford Camp; and D. A. Henderson to the *Pembroke*, for R.N. Barracks.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeons: H. S. Reid to the *Victory*, for Royal Naval Barracks. Surgeon Probationers: D. B. S. Jones to the *Anglia*, G. Pearson to the *Larne*, and J. E. Purnes to the *Beaver*.

ARMY MEDICAL SERVICE.

Colonel Bruce M. Skinner, M.V.O., is retained on the Active List and to be supernumerary (dated April 5th).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Herbert J. M. Buist, D.S.O., to be local Colonel, whilst serving in South Africa (dated Jan. 1st). Edward Augustine Hanly to be temporary Lieutenant-Colonel (dated March 1st).

Captain Dennis Embleton, 3rd London General Hospital, Territorial Force, to be temporary Major (dated Nov. 20th, 1914).

Temporary Lieutenant Robert J. D'A. Irvine to be temporary Captain (dated March 16th).

Supernumerary Major Dudley S. Skelton is restored to the establishment (dated March 5th).

Hugh Winchworth Macnamara, late Fleet Surgeon, R.N., to be temporary Major (dated March 6th).

Harold Albert Kisch to be temporary Captain (dated Feb. 17th). Thomas Guy Macaulay Hine is granted temporarily the honorary rank of Captain (dated March 11th).

Lieutenant Thomas H. W. Idris relinquishes his temporary commission (dated March 1st).

Wilfred John Pearson is granted temporarily the honorary rank of Lieutenant. Temporary Lieutenants Harold M. Cory and Charles J. Thompson relinquish their commissions (dated Feb. 7th).

The undermentioned to be temporary Lieutenants:—Dated Feb. 17th: Bernard Wallace, Harold Ernest Gamlen, Edward Leslie Horsburgh, and Thomas Twistington Higgins. Dated Feb. 18th: George Barbour Macgregor, Thomas Lovett, Samuel Constantine Westwood, Alfred Merrin, Thomas Francis Griffin, Matthew Arnold Swan, Edward Shairp Barnard Eames, George Arthur Borthwick, Horace Lloyd Mann, Wilkinson Overend, Hubert Walter Ward, Maurice John Mottram, Donald Francis Shearer, Alexander Lewis Grant, John Fraser Steven, and Austin Charles Giles. Dated Feb. 19th: William Henry Anderson and John Ferguson. Dated Feb. 20th: Lawrence Henry Carr Birkbeck, John Edward O'Loughlin, Thomas James Simpson Moffett, Robert Charles Matson, Edwin Cecil Hardwicke, Hugh Atwood Beaver, and Charles Wilkinson Brecks. Dated Feb. 21st: John Humphrey James Victor Coats. Dated Feb. 22nd: Stephen Walter Coffin, Leonard Graham Brown, George Henry Fullarton Graves, Gerald Schofield, and Percy East Lones.

The undermentioned to be temporary Lieutenants whilst serving with the Red Cross Hospital, Netley:—Dated March 13th: Eric Lancelot Kingsley Sargent and Arthur Rawdon Carrington Dooley.

INDIAN MEDICAL SERVICE.

The King has approved the grant of the temporary rank of Lieutenant in the Indian Medical Service to the undermentioned: Dated Nov. 17th, 1914: Charles Stiebel. Dated Nov. 19th, 1914: Shripat Govind Ranaday. Dated Nov. 20th, 1914: Satyendra Nath Mukerji. Dated Nov. 23rd, 1914: Sakria Nath Chaudhuri, Devarayadray Venkatia Giri, and Jehangir Kaikhusro Nariman. Dated Nov. 24th, 1914: Richard Charles Palmer Berryman and Graham Colville Ramsay. Dated Nov. 30th, 1914: Kaikushru Bezonji Kanga.

Dated Dec. 1st, 1914: Girdhari Lal Batra, John Barré de Winton Moloney, and Behramji Pestonji Sahawala. Dated Dec. 2nd, 1914: Bindashwari Prasad, Satyendranath Roy, Jotindra Mohan Das Gupta, Maung Ba Yin, and Probodhchandra Banerjee. Dated Dec. 3rd, 1914: Thomas Henry Bishop. Dated Dec. 5th, 1914: Shivax Sorabji Banker and Ian Douglas Grant. Dated Dec. 8th, 1914: Kaikhusru Kersaspji Dadachanji, Phirozeshaw Jamshedji Kolaporewalla, Ambujnath Bose, and Sobha Ram Kapoor. Dated Dec. 14th, 1914: David Perceval Oliver, Codanda Madiiah Ganapathy, and Madan Gopal Bhandari.

TERRITORIAL FORCE.

Royal Army Medical Corps.

South-Eastern Mounted Brigade Field Ambulance: Edgar Milwyn Jenkins to be Lieutenant.

3rd London (City of London) Field Ambulance: John Howard Jones to be Captain, and to be appointed Acting Transport Officer. George Watters Greene to be Lieutenant.

2nd East Lancashire Field Ambulance: Lieutenant Frederick Jeeves to be Captain (temporary).

Sanitary Service: Captain Herbert E. Corbin to be Major (dated Feb. 17th). David Thomas Rocyn Jones to be Captain, whose services will be available on mobilisation (dated March 17th).

2nd South Midland Mounted Brigade Field Ambulance: To be Lieutenants: John Cecil Stoyte Dunn and Alexander Rodger.

1st Lowland Field Ambulance: Captain William C. Murray to be Major (temporary).

2nd West Riding Field Ambulance: Major Harold Collinson to be Lieutenant-Colonel (temporary).

Attached to Units other than Medical Units.—To be Majors: Charles Rosser Bishop (late Major, 4th Battalion, Prince Albert's (Somerset Light Infantry)) and Captain Ernest Solly. Major David L. Todd to be seconded. To be Captains: Surgeon-Captain George D. Kettlewell, from Devonshire Royal Garrison Artillery; and Charles Ranald Handfield-Jones (late Surgeon-Captain, 24th Middlesex Volunteer Rifle Corps). To be Lieutenants: Alexander Fraser Wilson, James McGavin Deuchars, Hugh Boyd Cunningham, and John Russell Brodie Russell.

ORDER OF ST. JOHN OF JERUSALEM.

The King has sanctioned the following promotions in and appointments to the Order of the Hospital of St. John of Jerusalem in England:—As Knights of Grace: Colonel W. J. Will, A.M.S. (N.Z.), Lieutenant-Colonel F. Marsh, R.A.M.C. (T.F.), and Dr. J. Lumsden.

THE GLAMORGAN RED CROSS GAZETTE.

The February issue contains much of interest to Red Cross workers, who will doubtless find plenty of work with the coming of spring and increased activity at the front. The Welsh Hospital, An Ambulance Train, Experiences in a French Hospital, The Functions of the Auxiliary Home Red Cross Hospital, and How We Prepared an Auxiliary Hospital are among the contents of this useful little publication.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 9033 births and 6863 deaths were registered during the week ended Saturday, March 13th. The annual rate of mortality in these towns, which had been 20.7, 20.4, and 20.2 per 1000 in the three preceding weeks, further fell in the week under notice to 19.7 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 19.5, against a corresponding rate of 20.3 per 1000 in London. The annual death-rate last week ranged from 8.0 in Ilford, 11.0 in Edmonton, 11.4 in Burnley, 11.7 in Croydon and in Hornsey, and 11.8 in Coventry to 26.7 in Carlisle, 26.9 in Northampton, 27.2 in Stockton-on-Tees, 28.0 in Cambridge, and 30.4 in Bath.

The 6863 deaths from all causes were 177 fewer than the number in the previous week, and included 657 which were referred to the principal epidemic diseases, against numbers increasing from 511 to 618 in the four preceding weeks. Of these 657 deaths, 373 resulted from measles, 120 from whooping-cough, 77 from infantile diarrhoeal diseases, 51 from diphtheria, 21 from scarlet fever, and 15 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.9 against 1.8 per 1000, in each of the two preceding weeks. The deaths attributed to measles, which had increased from 207 to 331 in the four preceding weeks, further rose to 373 last week, and caused the highest annual death-rates of 3.8 in West Bromwich, 4.1 in Smethwick, 4.3 in Merthyr Tydfil, 4.7 in Northampton,

4.9 in Wolverhampton, 5.3 in Grimsby, 6.3 in Cambridge, and 7.9 in Darlington. The deaths referred to whooping-cough, which had been 135, 111, and 110 in the three preceding weeks, rose to 120 last week; the highest death-rates from this disease were 1.8 in Merthyr Tydfil, 1.9 in Eastbourne, 2.1 in Bootle, 2.3 in Wigan, and 2.8 in Gillingham. The fatal cases of diarrhoea and enteritis (among infants under 2 years), which had been 80, 75, and 71 in the three preceding weeks, rose to 77 last week, and included 25 in London, and 4 each in Birmingham, Liverpool, and Leeds. The deaths attributed to diphtheria, which had been 80, 72, and 64 in the three preceding weeks, further declined to 51 last week, of which 6 were registered in London, 4 each in Birmingham, Liverpool, and Manchester, and 3 in Bolton. The deaths referred to scarlet fever, which had been 32, 38, and 32 in the three preceding weeks, further fell to 21 last week, and included 6 in London, 3 in Birmingham, and 2 each in Liverpool, Wigan, and Bradford. The fatal cases of enteric fever, which had been 17, 13, and 10 in the three preceding weeks, rose to 15 last week, and included 3 each in Stoke-on-Trent and Bradford.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 2943 in the 15 preceding weeks, had further decreased to 2850 on Saturday last; 275 new cases were admitted during the week, against 295, 302, and 298 in the three preceding weeks. These hospitals also contained on Saturday last 1556 cases of diphtheria, 261 of measles, 62 of enteric fever, 14 of whooping-cough, and 3 of small-pox. The 1795 deaths from all causes in London were 14 in excess of the number in the previous week, and corresponded to an annual death-rate of 20.7 per 1000. The deaths referred to diseases of the respiratory system, which had been 459, 476, and 468 in the three preceding weeks, further fell to 443 last week, but were 220 above the number registered in the corresponding week of last year. The deaths from influenza numbered 54, against 60, 83, and 48 in the three preceding weeks.

Of the 6863 deaths from all causes in the 96 towns 206 resulted from different forms of violence and 498 were the subject of coroners' inquests, while 1830 occurred in public institutions. The causes of 57, or 0.8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Leeds, Bristol, Bradford, and in 50 other smaller towns. Of the 57 uncertified causes, 11 were registered in Birmingham, 7 in Liverpool, 5 in Blackpool, 3 each in Stoke-on-Trent and Preston, and 2 each in Gillingham, Reading, Bootle, St. Helens, Southport, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1266 births and 940 deaths were registered during the week ended Saturday, March 13th. The annual rate of mortality in these towns, which had been 22.8, 21.2, and 23.2 per 1000 in the three preceding weeks, fell to 20.9 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 22.7, against 19.5 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 10.2 in Kirkcaldy, 11.7 in Clydebank, and 15.5 in Kilmarnock to 24.3 in Falkirk, 25.3 in Leith, and 31.8 in Dundee.

The 940 deaths from all causes were 103 fewer than the number in the previous week, and included 131 which were referred to the principal epidemic diseases, against 131 and 145 in the two preceding weeks. Of these 131 deaths, 87 resulted from whooping-cough, 15 from measles, 13 from scarlet fever, 10 from diphtheria, 5 from infantile diarrhoeal diseases, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2.9, against 1.9 per 1000 in the English towns. The deaths attributed to whooping-cough, which had been 97, 89, and 91 in the three preceding weeks, fell to 87 last week, and included 39 in Glasgow, 25 in Dundee, and 9 in Edinburgh. The deaths referred to measles, which had been 13, 8, and 21 in the three preceding weeks, fell to 15 last week, and comprised 9 in Dundee, 5 in Glasgow, and 1 in Paisley. The fatal cases of scarlet fever, which had been 10, 11, and 9 in the three preceding weeks, rose to 13 last week, of which 8 occurred in Glasgow. The deaths attributed to diphtheria, which had increased from 6 to 15 in the four preceding weeks, fell to 10 last week, and included 5 in Edinburgh and 2 in Glasgow. The deaths of infants (under 2 years) referred to diarrhoea and enteritis, which had declined from 16 to 7 in the five preceding weeks, further fell to 5 last week, and comprised 4 in Glasgow and 1 in Aberdeen. The fatal case of enteric fever occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 265, 235, and 264 in the three preceding weeks, fell to 215 in the week under notice, but were 78 above the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 23, against 34 in each of the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 692 births and 602 deaths were registered during the week ended Saturday, March 13th. The annual rate of mortality in these towns, which had been 26.5, 27.6, and 27.4 per 1000 in the three preceding weeks, fell to 25.9 per 1000 in the week under notice. During the first ten weeks of the current quarter the mean annual death-rate in these towns averaged 26.0, against corresponding rates of 19.5 and 22.7 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 30.1 in Dublin (against 20.7 in London and 19.9 in Glasgow), 25.2 in Belfast, 25.8 in Cork, 15.2 in Londonderry, 14.9 in Limerick, and 9.5 in Waterford, while in the 21 smaller towns the mean death-rate was 25.3 per 1000.

The 602 deaths from all causes were 34 fewer than the number in the previous week, and included 37 which were referred to the principal epidemic diseases, against 38 and 36 in the two preceding weeks. Of these 37 deaths, 14 resulted from infantile diarrhoeal diseases, 12 from whooping-cough, 8 from measles, and 1 each from enteric fever, scarlet fever, and diphtheria, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1.6, against corresponding rates of 1.9 and 2.9 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 10, 5, and 11 in the three preceding weeks, further rose to 14 last week, and included 7 in Dublin and 4 in Belfast. The deaths referred to whooping-cough, which had been 12, 18, and 10 in the three preceding weeks, rose to 12 last week, and comprised 6 in Belfast, 5 in Dublin, and 1 in Cork. The fatal cases of measles, which had been 6, 8, and 8 in the three preceding weeks, were again 8 last week, of which 6 occurred in Belfast. The death from enteric fever was recorded in Cork and those from scarlet fever and diphtheria in Dublin.

The deaths referred to diseases of the respiratory system, which had been 168, 187, and 188 in the three preceding weeks, fell to 167 in the week under notice. Of the 602 deaths from all causes, 179, or 30 per cent., occurred in public institutions, and 10 resulted from different forms of violence. The causes of 25, or 4.2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0.8 per cent.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—

We are asked to state that hospitals in the County of London, or within nine miles of Charing Cross, desiring to participate in the grants made by this Fund for the year 1915 must make application before March 31st to the honorary secretaries, 7, Walbrook, E.C. Applications will also be considered from convalescent homes which are situated within the above boundaries, or which, being situated outside, take a large proportion of patients from London. Applications will also be considered from sanatoriums for consumption which take patients from London or which are prepared to place beds at the disposal of the Fund for the use of patients from London hospitals.

ROYAL DENTAL HOSPITAL, LEICESTER-SQUARE.—

At the fifty-seventh annual meeting of governors, held on March 11th, the Hon. Harry Lawson, M.P., a vice-president, being in the chair, the committee of management reported that 19,716 new patients had been treated during the year, their attendances being 55,104, the operations performed reaching the large total of 104,573; that the total amount received during the year was £8564 16s. 10d.; that the amount received from King Edward's Hospital Fund was £400; from the Hospital Sunday Fund, £141 15s.; and from the Hospital Saturday Fund £80 10s. A striking feature of the last half of the year's work had been the treatment of soldiers and recruits. The committee made an offer to the War Office, which was accepted, with the result that since the hospital reopened on Sept. 1st the total number of attendances exceeded 7000. The debt on the building is now £31,159 18s. 3d., and the yearly compulsory payments of principal and interest on the mortgage amount to £2400. The committee earnestly appeals for funds.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Midlothian Local Medical Committee.

THE third annual meeting of the Midlothian Local Medical Committee in connexion with the National Insurance Act was held at Edinburgh on March 11th. Dr. A. D. R. Thomson, for reasons of health, intimated his resignation as chairman. Dr. F. C. Fowler was elected chairman and Dr. T. D. Inch vice-chairman. The composition of the committee is the same as last year, with the substitution of Dr. C. W. Somerville in room of Dr. J. McG. Deuchars, resigned. Mr. J. Burnett Mackie was re-elected secretary. Dr. A. G. Robertson was elected to fill the vacancy in the representation of the committee on the Midlothian Insurance Committee in place of Dr. Thomson, resigned.

Edinburgh Royal Infirmary.

A meeting of the managers of the Royal Infirmary was held on March 8th, Lord Provost Inches presiding. It was reported that the patients in hospital at the last return numbered 883, and admitted during the last two weeks 493, making the total number treated 1376. The numbers dismissed cured were 299, relieved 134, otherwise 14, and died 32. The actual number of new cases treated during the past two weeks at the various out-patient departments were 1339, the majority of whom subsequently attended two or three times. In addition to these, there were 64 patients resident at the Convalescent House, Corstorphine. The following appointments for six months from April 1st were made:—Resident physicians: Dr. J. Roderick Bulmna (to Dr. Graham Brown), Dr. R. C. Rogers (to Dr. F. D. Boyd); resident surgeons: Dr. Henry J. C. Gibson (to Professor F. M. Caird), Mr. C. M. G. Elliott (to Mr. C. W. Cathcart), Dr. I. F. Longley (to Mr. D. Wallace), Dr. I. K. F. McLeod (to Professor H. A. Thomson), Dr. James B. Hogarth (to Mr. A. Miles), and Mr. W. Douglas Yuille (to Mr. N. T. Brewis); non-resident house physician: Mr. Maurice G. Hannay (to Dr. Norman Walker); clinical assistant: Mr. B. S. Raj (to Dr. Sim). Dr. C. W. MacGillivray recalled that an appeal to the citizens of Edinburgh had been made to provide beds in case of such an emergency as a naval raid. The naval raid, however, had not occurred, but four ladies who had promised beds had now presented them to the infirmary, so that they now had seven beds fully equipped through the generosity of these ladies.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

An Antigangrenous Serum.

ON March 1st Dr. Roux, Director of the Pasteur Institute, in the name of M. Weinberg, made a very interesting communication to the Académie des Sciences. Medical officers generally have noticed since the beginning of the war the large number of wounded who have been attacked with gaseous gangrene. This serious disease—manifested by a tissue emphysema crepitating under the finger and a rapid and intense development of the phenomena of decomposition—if it does not always cause death, in many cases necessitates amputation. Therapeutic procedures have been employed, some

of which have had happy effects, but their value has in nearly every case been disputed. The problem was to find a powerful therapeutic agent. Among the various bacteria which propagate in gangrenous wounds, and which have been classified, M. Weinberg has discovered a new bacillus. He had examined more than 50 gangrenous wounds and in all this bacillus was found. On cultivation and inoculation into guinea-pigs the bacillus developed rapidly, and the animals presented symptoms similar to those presented by patients with gaseous gangrene, and died therefrom. After several attempts he found a serum capable of destroying the activity of the bacillus. He injected the serum into a number of guinea-pigs, following this up with an injection of the gangrene bacillus. Into a control group the bacillus alone was injected. The latter animals died in 36 hours. The others soon recovered their health. When he injected the serum and the virus simultaneously the disease did not develop. When the serum was injected five hours after the injection of the virus the disease appeared, but the animal finally recovered. When injected 10 hours after the virus some of the animals recovered, others died, though considerably later than the controls which had received the virus alone. In the case of animals, therefore, this serum is clearly possessed of curative properties. A first trial gives ground for hoping that it will prove equally successful in man. M. Weinberg has injected a wounded man with a dose of 22 c.c. and an improvement has already taken place in his condition.

A School for Crippled Soldiers.

The French Government has decided on the establishment of a national school for soldiers crippled by injuries received in war. The school will contain all the necessary apparatus, so that after their medical and surgical treatment is finished they may undergo a course of functional re-education. This will be followed, when their physical condition permits them to work, by a suitable industrial education, thus providing the victims of the war with a means of livelihood. The institution will be installed in the vast and convenient buildings of the Maison de Santé de St. Maurice, in the Department of the Seine, which can accommodate from 600 to 700 inmates. Near it are extensive workshops, which will lend themselves admirably to the organisation of technical instruction for the crippled. The Government will carefully avoid prejudicing institutions on the same lines that have been created recently or are about to be created by private enterprise. On the contrary, the Government school should stimulate them.

Gunshot Wounds of the Thorax.

While many gunshot wounds of the thorax heal readily, the most minute precautions should always be taken to prevent certain after-mishaps. It is of the first importance to guard these patients against chill, for the wounded lung in the neighbourhood of a bullet track affords a ready focus for secondary traumatic pneumonia to complicate the condition. In regard to these cases M. Reynier recommends a long surveillance to protect them against all possibility of chill or fatigue. The surgeon, he says, should never be beguiled by appearances into discharging these patients prematurely, but should grant only convalescent leave for them to go to their families. With prolonged rest and proper nourishment the absorption of the blood effused by the

pleura is gradually accomplished. These wounds markedly lessen the patient's resistance, creating in him a state of organic debility that must be energetically combated. Such patients, in short, are really anæmics, and as such have need of a stimulating and upbuilding medication.

March 16th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Canadian Hospitals for the War.

THE Dean of the Medical Faculty of McGill University, Montreal, Dr. H. S. Birkett, is in command of the University of McGill Base Hospital and has drawn up the personnel, which has been provisionally approved by the Militia Department of Canada. Dr. H. B. Yates, the second in command, is Assistant Director of Medical Service for the Fourth Canadian Military Division and President of the Montreal branch of the Canadian Red Cross Society. Other officers will be Dr. J. M. Elder, Dr. John McCrae, Professor J. George Adami, Dr. W. H. P. Hill, Dr. E. W. Archibald, Dr. A. Howard Pirie, Dr. L. J. Rhea, Dr. W. G. Turner, Dr. G. P. Howard, Dr. H. M. Little, Dr. W. B. Howell, Dr. C. K. Russel, Dr. W. Hutchinson, Dr. J. C. Meakins, Dr. W. W. Francis, Dr. J. A. MacMillan, Dr. R. H. M. Malone, and Dr. L. H. McKim. Mr. Lewis L. Reford and Mr. Revere Osler, a son of Sir William Osler, are supernumeraries. Over a hundred medical students have volunteered to serve with the hospital, and although as yet no appeal has been made for funds numerous gifts have already been received.

The University of Toronto, through its Medical Faculty, is offering to supply a Base Hospital, which will be composed of 1040 beds. Should this offer be accepted it will be wholly recruited from the medical staff and the medical students of the University of Toronto, and will be got ready to send to England by April 1st for use as the War Department sees fit. The equipment of the hospital will mean that 450 students and lecturers and professors will be taken away from the work of the Medical Faculty, which, counting those already at the front, is materially reduced. The 84 nurses who would accompany the hospital, it is proposed, will be taken from the various hospitals in Toronto affiliated with the University.

New Sanitarium Offices.

The National Sanitarium Association of Canada has just opened fine new executive offices in Toronto. This has been made possible through the generosity of Mr. W. J. Gage, of Toronto, who contributed \$100,000 for the purpose, and who has been a pioneer in fighting tuberculosis throughout Canada. Since the campaign against tuberculosis was inaugurated in Ontario some 18 years ago the deaths in that province have decreased from 2800 to a little over 2000 annually. Toronto has the lowest death-rate from tuberculosis compared with any American city of 300,000 population. In connexion with this new building there are examination rooms for the tuberculous poor, rooms for the examination of private patients, headquarters for chief physicians, X ray room, a lecture-room, and a free dispensary. Mr. Gage has also given \$10,000 for scholarships in connexion with research work in tuberculosis.

Deaths in Ontario in 1913.

The number of deaths registered in Ontario in 1913 was 34,317, a ratio of 12·7 per 1000 of the population. This is an increase of 2167 over 1912. Typhoid fever and diphtheria are decreasing annually. The deaths from typhoid were 446; diphtheria, 339. The deaths from tuberculosis were 2294, being 85 per 100,000 of the population, a decrease of 2 per 100,000 since 1912. Of the total deaths in the province, 6·3 per cent. were from tuberculosis, a decrease of 0·7 per cent. over 1912. Of this number 36·7 per cent. took place in the cities, 7·4 per cent. in the towns; 55·9 per cent. took place in the rural municipalities. Pneumonia claimed 2076; infantile diarrhoea, 1993; Bright's disease, 1070; heart disease, 2829.

Toronto, Feb. 25th.

Obituary.

SIR GEORGE TURNER, M.B., D.P.H. CANTAB.,
L.R.C.P. LOND., M.R.C.S. ENG.,
LATE MEDICAL OFFICER OF HEALTH OF THE TRANSVAAL.

WE much regret to record the death of Sir George Turner, who, at the time of his knighthood on the King's own initiative in 1913, was by the *Times* aptly described as "Another Father Damien." His death occurred at his residence, Colyton, Devon, on March 12th, in his eightieth year.

Sir George Turner was educated at Cambridge University and at Guy's Hospital and qualified L.R.C.P. Lond., M.R.C.S. Eng. in 1872. Later he graduated at Cambridge in medicine, taking also the Diploma in Public Health. He was appointed medical officer of health and public analyst of the borough and port of Portsmouth, and physician to the Portsmouth Fever Hospital, which posts he relinquished in 1880 on being appointed medical officer of health of the Hertfordshire and Essex combined sanitary district. This post he occupied for some 15 years, and for the greater part of the period was lecturer on hygiene at Guy's Hospital and an examiner in public health to the Conjoint Board in London. In 1895 he entered the civil service of Cape Colony as medical officer of health, where his undoubted fitness for sanitary work soon became manifest in the improvement of the public health. Rinderpest, which at the time of his appointment was doing great damage among the cattle, was being investigated by Professor Koch. On the recall of the great German pathologist Dr. Turner continued the work and was appointed in 1897 to the charge of the Kimberley rinderpest station, where for five years he laboured assiduously to stamp out the disease. This he succeeded in doing, and his services must have saved Cape Colony an incalculable sum of money. The Cape Colony Government then decided to close the laboratory, but the serum produced there was so urgently needed in Rhodesia and Egypt that the work was continued for a time at the personal expense of Mr. Cecil Rhodes.

On the outbreak of the South African War Dr. Turner was seconded as sanitary adviser for service with Lord Roberts in the Transvaal, and supervised the military hospitals and concentration camps at a time when the ravages of typhoid fever were severe. At the close of the war, at the instance of Lord Milner, he was appointed medical officer of health of the Transvaal, when he found time among other activities vigorously to prosecute

the war against rinderpest. A serum factory was established at Dassport from which the serum was sold to Egypt and Natal with successful results. The work which Sir George Turner did for the public health of South Africa was important and of lasting value, but his name will always be associated with his labours in connexion with leprosy, to which disease he unfortunately fell a victim, though, save to those within his own private circle, the fact was not made public till within a few weeks of his name appearing in the list of New Year Honours in 1913. As medical superintendent of the Pretoria Leper Asylum he was brought into constant association with this most lamentable group of sufferers. In 1901 there were about 90 patients in the asylum, but his untiring labours on behalf of those suffering from the disease brought an ever-increasing number of patients under his care, and at the end of the seven years during which he was in charge the number had grown to 400. All his spare time was given to the alleviation of their sufferings, and the careful clinical study which he made of each case soon established him as an authority on the disease. It was hoped that an arrangement would be made with the Transvaal Government which would enable him to continue in his good work, but the authorities did not appear to see the necessity, and he retired from the post in 1908. On his return to this country he continued to prosecute his bacteriological studies, even after he knew that he had fallen a victim to the disease, hoping to advance our knowledge in the practical therapeutics.

Outside the medical profession few recognised the great services which Sir George Turner had rendered to humanity, but his work in South Africa, to those who impartially judge it, must always remain a lasting monument to his name. Sir George Turner was a widower and leaves four sons, one of whom graduated in medicine at Aberdeen University in 1897.

WILLIAM MORTIMER, M.D., C.M. ABERD.

Dr. William Mortimer, who died at his residence, Turriff, Aberdeenshire, on March 6th, at the ripe age of 82 years, entered on the study of medicine at Aberdeen in 1855. In the second year of his studentship he went for a voyage as surgeon on board a Greenland whaler, and on his return acted as assistant to two local medical practitioners in succession. Resuming his interrupted medical studies he graduated as M.D., C.M. at the University of Aberdeen in 1861, and almost immediately commenced to practise in Turriff, where he has since resided. Dr. Mortimer was particularly interested in the Volunteer movement, and for some 30 years was connected with the 2nd Volunteer Brigade of the Gordon Highlanders, from which he retired about 15 years ago with the rank of surgeon-lieutenant-colonel. He was joint medical officer to the old parochial board at Turriff, afterwards to the parish council, and medical officer of health to the burgh. He leaves a widow, a married daughter, and a son (who is now serving his country in the army) to mourn their loss.

CHARLES JOSEPH FAGAN, M.B., B.CH. DUB., SECRETARY TO THE PROVINCIAL BOARD OF HEALTH, BRITISH COLUMBIA.

Dr. Charles Joseph Fagan died at Esquimalt, Vancouver Island, on Feb. 10th, at the age of 57. He was born in county Westmeath, Ireland, and received

his education in Dublin, where he graduated at the University in 1883. He then went to British Columbia, where, after being superintendent of St. Mary's Hospital, New Westminster, he was, some 20 years ago, made medical officer of health of the province. He organised the sanitary service of the province very skilfully, paying particular attention to the prevention of tuberculosis, his special satisfaction being the establishment of the Provincial Sanatorium at Tranquille, on the mainland, in the dry belt, between the Coast Range and the Selkirk Mountains. He was also official analyst for the Province of British Columbia and registrar and secretary of the College of Physicians and Surgeons. The Premier, Sir Richard McBride, has characterised him as one of the most efficient servants who had ever been in the employ of the Government, and his death as a real loss.

GIUSEPPE RESINELLI,

PROFESSOR OF MIDWIFERY AND GYNÆCOLOGY IN THE INSTITUTE OF HIGHER STUDIES OF FLORENCE, AND DIRECTOR OF THE OBSTETRIC AND GYNÆCOLOGICAL CLINIC.

Professor Giuseppe Resinelli died on March 1st from an attack of acute pneumonia at the age of 49. He was born at Lecco in 1865, took his degree at Pavia in 1890, and his "libera docenza" in obstetrics and gynæcology in 1895. In 1901 he was director of the Foundling Institute at Ferrara, in 1902 he became professor at Cagliari, and in 1903 professor at Parma. In 1906 he succeeded Professor Pestalozza at Florence. He was an indefatigable worker, a clear thinker, a sound teacher, and a brilliant operator, and beyond all these a man of the widest culture and sympathies. Scientifically he will be best remembered by his writings on chorion-epithelioma. In Florence his memory will rest securely on the gratitude of his patients and students. A man of the simplest tastes, money made no appeal to him personally. Generous to a fault, he never hesitated to sacrifice his own well-being whenever he could be of help, and wore himself out in the service of others. His early death robbed him of the wider professional reputation which would certainly have been his, and deprived Italy of a son who would have brought her further honour in the world of science.

THE NEW HOSPITAL FOR WOMEN.—The annual meeting of the governors of this hospital took place on March 11th, when the Duchess of Marlborough presided. The annual report showed an increase of 307 in the number of in-patients treated during 1914, as compared with the number for 1913. This was shown to be due to the opening, in August, 1913, of the Rosa Morison House of Recovery at New Barnet. Lady Jellicoe, Mr. Stephen Paget, the Rev. Percy Dearmer, and Dr. Louisa Garrett Anderson were among the speakers.

INSURANCE ACT DRUG TARIFF.—We understand that the long-expected committee to investigate the working of the Drug Tariff under the Insurance Act, which was probably delayed in consequence of the general disorganisation induced by the war, has at length been appointed, and that its composition is as follows: Sir Rowland Bailey, C.B., M.V.O. (chairman); Dr. John Adams, member of Council of the British Medical Association; Dr. Alfred Cox, medical secretary of the British Medical Association; Mr. James P. Gilmour, member of Pharmaceutical Society of Great Britain; Mr. J. F. Tocher, Aberdeen; Mr. R. V. Vernon, Treasury; Mr. S. P. Vivian, an assistant secretary in the National Health Insurance Commission (England); Mr. W. J. Uglow Woolcock, secretary and registrar, Pharmaceutical Society. Joint Secretaries: Dr. E. W. Adams and Mr. James Rae, National Health Insurance Commission (England), Buckingham Gate, S.W., to whom communications should be addressed.

THE BELGIAN DOCTORS' AND
PHARMACISTS' RELIEF FUND.

THE subscriptions to the Fund during the week have been smaller than usual, but the amount of money which has been promised or paid to local funds, and which has not yet reached the treasurer, is growing.

A meeting of the executive committee was held on March 11th when the form of a circular statement dealing with the activities of the Fund was settled. A report of a sitting in Brussels of the "Aide et Protection aux Médecins et Pharmaciens Belges" was received through Mr. Herbert Hoover, and showed that this society, which is substantially the body whose representations formed the starting point of the British Fund, is doing good work in Belgium by succouring doctors and pharmacists in their need. The Belgian society duly acknowledged at that meeting the receipt of the 50 cases of medical material from the British Fund.

MANCHESTER AND DISTRICT.

We learn from Dr. E. M. Brockbank, secretary to the Manchester and District Fund, that the total amount received up to March 14th was £444 13s. from medical men. The following subscriptions have come to Dr. Brockbank, additional to those already acknowledged:—

	£	s.	d.		£	s.	d.
Dr. A. Hill Griffith	5	5	0	Dr. J. M. S. Preston	1	1	0

Mr. Robby Gardner ...	0	5	0
Mr. W. Greenwell ...	0	5	0
Mr. W. Clark ...	0	5	0
Mr. R. W. Wilson ...	0	5	0
Birmingham Local Com- mittee (per Dr. Robert Saundby), eleventh donation—			
Dr. E. StJohn White- house ...	1	1	0
North of England Branch of Belgian Doctors' and Pharmacists' Relief Fund (per Dr. James Don, Hon. Sec.), third dona- tion—			
Dr. George Duncan ...	2	2	0
Dr. James Chalmers ...	2	2	0
Dr. T. W. Hay ...	1	0	0
Dr. Crerar ...	1	1	0
Association of Certifi- cated Dispensers (Society of Apothe- caries of London) ...	16	4	6

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd. £8000 had passed into the treasurer's hands by Tuesday last, the sum not including the Scottish and Irish and several large local funds.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments kindly contributed by Dr. W. A. H. Barrett, Melbourne, Australia.

DONATIONS AND BEQUESTS.—The late Mr. Edward Wright, of Leamington, has bequeathed £1000 each to the Royal Hospital for Incurables, Leamington, the Warneford and South Warwickshire Hospital, and the Ellen Badger Cottage Hospital, Shipston-on-Stour; £500 each to Dr. Barnardo's Homes and the National Refuges for Homeless and Destitute Children, Shaftesbury-avenue, W.C. He also left £100 each to his two nurses. Further sums of £25,000 will also accrue to the Warneford and South Warwickshire Hospital and the Ellen Badger Cottage Hospital.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The annual report of the Royal Albert Hospital, Devonport, for 1914, states that during the year 703 in-patients were admitted (the average stay of each being 24.9 days), as compared with 711 in 1913. The out-patients numbered 3771. The financial statement showed that during the year £3143 were realised by selling invested funds, and there remained an unfavourable balance of £263. The Royal Albert Hospital has been in existence for over 50 years, and it performs a most useful work in Devonport; it is, therefore, much to be regretted that its financial position is so unsatisfactory. The committee make a strong appeal for more subscriptions, and it is to be hoped that this will be liberally responded to.

The War.

THE CASUALTY LIST.

THE casualties among officers in the Expeditionary Force reported since our last issue include the names of Captain Harry Vivian Byatt, R.A.M.C., and Lieutenant Theodore Stewart Lukis, M.D. Lond., M.R.C.P. Lond., 13th (Kensington) Battalion, London Regiment, died of wounds; and Lieutenants J. G. Priestley, W. W. Ingram, W. Ormsby, D. C. Turnbull, and G. P. Selby, all of the Royal Army Medical Corps, wounded.

Lieutenant Lukis, of the 13th (Kensington) Battalion, London Regiment, who died of his wounds at Boulogne Base Hospital on March 15th, was the eldest son of Surgeon-General Sir Pardey Lukis, Director-General, I.M.S. He obtained his commission in September, and was wounded in the trenches on March 13th.

THE HONOURS LIST.

The Second Class of the Indian Order of Merit has been conferred on 1st Class Sub-Assistant-Surgeon Nagindar Singh, I.S.M.D., for gallantry and devotion to duty while serving with the Indian Army Corps, British Expeditionary Force.

In the list of appointments as C.M.G., which was published in THE LANCET on Feb. 27th, the name of Lieutenant-Colonel Gerald Cree was omitted. The list now appears in the *London Gazette*.

CAPTAIN ARTHUR MARTIN LEAKE, V.C. (CLASP).

Temporary Lieutenant A. Martin Leake, V.C., who was recently awarded the distinction of a clasp, has been gazetted temporary Captain, R.A.M.C.

LORD KITCHENER ON THE WORK OF THE ARMY MEDICAL SERVICE.

In his speech in the House of Lords on March 15th Lord Kitchener paid a high compliment to the Royal Army Medical Corps and testified to the great utility of antityphoid inoculation in the following words: "The health of the troops has been remarkably good, and their freedom from enteric fever and from the usual diseases incidental to field operations is a striking testimony to the value of inoculation and to the advice and skill of the Royal Army Medical Corps and its auxiliary organisations."

THE WAR AND THE PRICE OF DRUGS.

Since the last note dealing with the effect of the war on the supply of drugs appeared in THE LANCET the general tendency of values has continued to be in an upward direction, and the prices of drugs which had formerly been supplied by Germany have been steadily increasing until at the present time the figures quoted for some of the synthetic products are remarkably high. One of the most notable examples is acetylsalicylic acid, which is now quoted at seven times the price at which it could be obtained before the war; the advance in the price of this drug has been particularly marked during the last week or two, and there is good reason to suppose that the decision of the Board of Trade to allow the word "aspirin" to be used to designate acetylsalicylic acid, from whatever source obtained, has given a fillip to the demand for this drug, which,

especially in its compressed form, is being advertised on a more extensive scale. No doubt the price would have continued to advance even if the demand had been normal, for the supplies in this country at the outbreak of war were not large, and the amount obtainable since then from neutral countries has been limited, while our own manufacturers are not as yet able to produce the drug in sufficiently large quantities to supply the deficiency. Salicylic acid and salicylate of soda are also becoming very scarce; the price of the former is now about seven times the figure quoted before the war and of the latter nearly eight times the pre-war figure, and in all probability the advance will continue until the market is relieved by the fresh supplies which are expected from France in due course. But even if an abundance of supplies were procurable the price would be much in excess of the normal on account of the high cost of carbolic acid, the raw material from which salicylates are produced. A not unimportant factor in the recent accentuation in the advance of these and other synthetic drugs is the promised blockade—not the German “blockade,” but the British. Until recently the United States and other countries had been obtaining fair supplies of drugs from Germany and had been able to send their surplus stocks to this country; the decision of the allies, however, to put a stop to Germany's foreign trade will have the effect of preventing America from obtaining regular shipments from Germany, with the result that America may have no surplus to ship to this country. This, of course, applies to most of the drugs which were formerly procured from Germany. Phenacetin and acetanilide are each about four times the pre-war price and phenazone is double. Cocaine is more than double the price quoted before the war, but the present quotation cannot be considered abnormally high, and the figure at which this drug had been selling for some time prior to August last year was unusually low. The demand for morphine and codeine from the medical services of the allied armies continues extremely large, and makers find it no easy matter to keep pace with it. In view of the vastly increased consumption of these alkaloids and the cutting off of supplies of Turkey opium, it is not remarkable that prices have advanced very considerably since the war began; in fact, it is rather surprising that they are not higher than they actually are. Fortunately good supplies of Persian opium have been available, and some business has been done in Indian opium, although, owing to the low morphine content of the latter, it is not altogether suitable for manufacturing purposes. Stocks of atropine are extremely low and prices correspondingly high. Chloral hydrate costs rather more than double its pre-war price, as also do the bromides. A drug which is affected by the war in a curious way is cod liver oil; in ordinary times a good yield from the Norwegian fishing generally means low prices, for the demand from year to year is much the same. Up to now the present season's fishing has undoubtedly been good, but the quotations have advanced rapidly since the beginning of the season, until at the time of writing they are about double those quoted when the season commenced about two months or so ago. To some extent, of course, this advance is due partly to the increased cost of freight and insurance, but the main cause is the excessive buying by the Germans on account of the scarcity in Germany of industrial oils; it is also suspected that the Germans may be

using cod-liver oil as a food, but for whatever purpose it is required the fact is established that enormous quantities of the oil are going to Germany, with the result that available supplies for the rest of the world's requirements are substantially reduced and prices higher in consequence. The above are a few marked examples of drugs that have advanced in price in consequence of the war, but the general tendency of the values of nearly all drugs is in an upward direction.

LOCAL AUTHORITIES AND NAVAL AND MILITARY SERVICE.

In a circular on the organisation of labour, issued on March 11th, the Local Government Board, while acknowledging that local authorities generally have done much to facilitate enlistment among their eligible employees, urge that

At a time when the vital interests of the country imperatively require that as many fit men as possible should be added to the Army, when the manufacture of munitions of war is hampered by lack of labour, and when the same cause gives rise to difficulties in the supply and transport of food, fuel, and other necessities only men who are indispensable for the work of the local authority should be refused permission to enlist; that artisans who belong to trades needed in the arsenals, dockyards, and armament factories should, wherever possible, be released and encouraged to find employment there; and that where there is a demand for labourers on the railways, in the docks, and on farms, &c., the local authority should facilitate the transfer to those employments of any men who can be spared, and who can there find suitable occupation and remuneration. In pursuance of this policy it will be necessary to economise labour to the greatest extent possible, and, where substitutes are needed, to engage only men who are not eligible for the army and not suited for the occupations to which labour should be transferred. There are some posts in which the employment temporarily of women in place of men may be practicable.

The circular goes on to state that the inception of relief works recommended at the beginning of the war to obviate distress from unemployment has now happily become unnecessary owing to the rapid recovery of trade, the enlistment of large numbers of men, and the execution of war contracts, and should be avoided, except such as are of pressing necessity either for reasons of public health or on account of war requirements. The schemes that have been prepared will become of the greatest value again when the war is over and men return from the army and war contracts cease. The Local Government Board in this connexion call attention to their circular of August 21st entitled “Officers of Local Authorities on Naval and Military Service,” wherein it is laid down that local authorities may properly keep open the places of officers in their employ who join His Majesty's Forces with their permission, and suggest that a similar view might apply to those persons in the employ of such authorities who in the present emergency enter other employments as suggested in the circular.

THE HEALTH OF THE SWISS ARMY.

At the beginning of the European War Switzerland had its whole army of 400,000 men under arms. After a month this number was reduced to 300,000 and at the end of the year to three divisions, numbering together about 75,000 men, who were especially guarding the Italian and Franco-German frontiers. As the whole army can be called in at a couple of days' notice this number suffices. The whole of the three divisions which have been doing

service for seven months at a stretch have just been dismissed and replaced by three other divisions. The condition of the troops is excellent, only about 30 to 40 cases of death having occurred per month, the morbidity has been small, and the general physique of the men has greatly improved. There have been 7 cases of epidemic cerebro-spinal meningitis in the barracks of Zürich, with 5 deaths, but no fresh cases have been reported. The patients are doing well. The barracks have been evacuated.

FROST-BITE.

Mr. R. H. Jocelyn Swan read a valuable paper recently before the Clinical Section of the Royal Society of Medicine on So-called Frost-bite, in which he said that during the last few months a large number of soldiers had been incapacitated from duty owing to a painful condition of the feet which had received the name of frost-bite. The subject deserves all the attention which he gave it, and we hope that discussion of it may bring out some points not only in the pathology and treatment of the affection, but also in its prevention. Mr. Jocelyn Swan said:—

I have now seen just over 100 of these cases, 80 of which have been admitted into the wards of the Royal Herbert Hospital. Almost without exception these men have been subjected to long standing in the trenches without any opportunity of active exercise or change of position other than that of sitting down with their feet dependent. Further, their feet have been continuously wet and often covered with mud and thawing snow and slush. I have made careful inquiries in all cases as to the condition of their boots and clothing, and find that they nearly all wear boots quite loose, in fact, usually one or two sizes larger than in ordinary life, and in only two cases could I find any admission of having more than one pair of socks on. Further than this, they declare that bootlaces and putties have not been tied tightly. Hence the one condition which seems applicable to all cases is the continuous standing with wet feet. In connexion with this I had one case in which frost-bite occurred in the fingers. This patient was affected in both feet and in the fingers of the right hand; at the time he had a wet woollen glove on the right hand while the left, which was unaffected, was ungloved. The patient states that the foot first feels cold and numb, but that he is sometimes able to restore warmth to it by stamping the foot on the ground. On trying to walk the front part of the foot is insensitive and he feels as if he is walking on his heel. Patients thus affected are often, from force of circumstances, obliged to remain in the trenches until darkness comes on before they can be moved to the field dressing station, during which time the causative factor continues and the condition increased by the swelling which takes place in the boot foot. When the boot is removed the swelling becomes more marked, and in a few cases I have been told that the skin of the foot was blistered. In a few earlier cases the condition was perhaps made worse by warmth, but this has been exceptional in my experience.

It should be remembered that any descriptive account of these cases is from one's personal experience in an English base and that patients are seen three or more days after the onset of the affection. The cases present themselves in two distinct groups—one in which there is little gross change in the tissues of the feet, but in which are marked subjective changes; the other in which tissue destruction has occurred leading to gangrene varying from a superficial skin lesion to a massive gangrene affecting the toes or even the whole foot, of which I hope to show some examples taken by colour photography. In these cases of gangrene I was unable to obtain any evidence of the increased intensity of cold or any difference in the primary treatment applied to the feet. The cases in which no actual lesion is present are by far the most numerous. The skin of the anterior part of the dorsum of the foot may be slightly oedematous, of slight bluish colour, and often rather dry and scaly. The patients complain of pain of an aching, swollen,

or bursting character, which is most apparent at night and keeps them awake. On a more critical examination most of these cases show a marked area of cutaneous anaesthesia and analgesia extending in "stocking form" from the points of the toes to the heads or even to the bases of the metatarsus, whilst the joint sense and vibration sense may be lost. In some cases the cutaneous change is one of marked hyperaesthesia, the slightest touch even of a piece of cotton-wool provoking marked pain. I am satisfied that the hyperaesthetic condition does not precede or follow the anaesthetic, as I was inclined to think at first, and I can give no reason for the different condition when the local appearance is the same. Whichever condition is present, however, there is often marked pain on passive movements of the toes or upon applying any pressure upon the metatarsal portion of the foot. I am not inclined to look upon this condition in any way as a "neurosis," as has been suggested, but rather as a tissue change due to vaso-motor constriction maintained for some time. The cases which present more interest from the surgical point of view are those in which there is some actual gross lesion of the tissues. In the simplest form is a small area into which hæmorrhage has occurred, the skin over it being discoloured, dry, and wrinkled. This area may slowly slough, leaving an ulcerated surface which is slow to heal. In one case under my care the under surfaces of each great toe were affected, the one as a slight cutaneous discolouration, the other as a distinct ulcer covered by dull granulations. In a more advanced condition one or more toes are actually gangrenous, presenting a dark, dried, wrinkled appearance with the rapid formation of a pronounced line of demarcation—the typical appearance of dry gangrene. In the several cases under my care it has been noticed that the great toe has been more seriously affected than the others, and when all the toes are affected the line of demarcation has become progressively near the periphery towards the outer side of the foot. These cases of dry gangrene are much best let alone, as the gangrenous part slowly separates off leaving a healing granulating area, from which it may be necessary later to remove any prominent piece of bone. In one case under the care of my colleague, Mr. C. Rowntree, separation took place behind the head of the metatarsus, and no operative interference was necessary. I should remark here that in cases in which actual gangrene has taken place it is more usual for only one foot to be thus affected, and I have been unable to discover any physical reason for this when apparently the same causation factors were present on both sides. In addition, the gangrenous areas do not present any relation to any particular points of pressure that would occur on standing, but rather affect the peripheral parts of the extremity. In three cases under my care a further extension of the tissue destruction had occurred, accompanied by rapid sloughing and a condition of moist gangrene, the terminal part of the foot being blackened, whilst the dorsum and lateral aspects were occupied by areas of superficial gangrene. There was much exudation of foul pus. The skin quickly separated with rapid infection of the tarsal and metatarsal joints. In two of these cases the condition was unilateral, and one of them developed tetanus on the fourteenth day, the spasms being particularly severe, and death occurred after four days. The third case is the most severe which I have yet seen. Both feet were involved, the right more than the left. The patient was extremely ill, having frequent rigors, with temperature reaching 106° F. On the right side the tarsal and ankle-joints were involved and I amputated the limb through the lower third of the leg. He improved for a few days; then recommenced a septic temperature, and as he was obviously going down hill rapidly I amputated the left foot through the ankle-joint, cutting through purulent tissues in fastening the flaps. From that time he commenced to improve and is now doing very well. I might remark that I have at present under my care a patient who has exactly the same symptoms as I have described in one foot with discolouration and ulceration in two toes, but who has not been out of England, but lived in barracks and who has not been subjected to any long exposure with wet feet.

Of the treatment of these cases there is not much to be said. In the majority of them presenting subjective symptoms of aching and anaesthesia I find it best to keep the patient in bed with the limb raised, to dry the foot with

spirit, and cover it with wool after dusting with boracic acid powder. Twice a day gentle massage is resorted to and in some cases weak faradism is applied, but I have found no advantage from electric baths. The aching pain is usually relieved by aspirin. Where the skin is very discoloured from underlying hæmorrhage I treat them in the same way, but where actual tissue destruction has occurred the foot is well cleaned and painted with 2 per cent. solution of iodine in spirit. When a line of demarcation appears the surface is wrapped in cyanide gauze, which is changed daily until the part is easily removed; and I would much rather await a natural separation than perform any amputation which must necessarily sacrifice a greater amount of the foot in the formation of the necessary flaps. Where moist gangrene is met with, and especially where toxic absorption has taken place, amputation just above the gangrenous area is required, but it is not necessary to sacrifice a lot of tissue by dividing the limb some distance from the highest point of gangrene. In one case I did a Syme's amputation and found pus in the tendon sheaths in front of the ankle, whilst there was a sloughing ulcer behind the heel. Very few sutures were put in and the stump drained with a good result.

With regard to prophylaxis, it is probably to the preventive treatment of this condition that attention should be directed. To my mind the condition, whatever its true pathology, is more due to the prolonged maintenance of a dependent position of the feet, wet from soakage from the slushy mud in the trenches, without any opportunity of exercise or of drying the feet, rather than to the severity of frost. It is perhaps noteworthy in this respect that the frost-bite known to Alpine climbers is more likely to occur when a thaw sets in than when severe frost is present. Perhaps with the approach of spring and better weather these cases may not occur, but there is no certainty that the present campaign will not go through another winter, when our soldiers may be fighting in even more severe climatic conditions than have already been experienced. Cannot we therefore arrange that their feet be better protected from wet when fighting in quarters where active movement is impossible? The regulation military boot cannot be improved upon as far as quality goes, but no ordinary boot will prevent water getting in over the top. The thought occurs of some form of gum boot, but these would necessarily much impede movements in attack or defence. Waders as used by ardent fishermen are too expensive for general supply, but have been a boon to those fortunate enough to possess them; and I think some good might be found from the use of thin mackintosh in the form of a stocking outside the sock but inside the puttee. This might retain any body moisture, it is true, but already the Canadian forces at the front have improvised mackintosh in this way with good results. I learn, too, that a similar condition to that which we have been seeing also occurred in the recent Balkan War from the long-continued damp to which the soldiers' feet were subjected. Another form of preventive treatment to which attention might be directed is that of thoroughly anointing the feet with an abundance of vaseline, and I understand that the free use of whale oil on the feet has been very effectual in preventing the trouble occurring. If, too, the boots were large enough to allow some play of the toes by muscular effort, and the men instructed to do it, the circulation in the extremities would be assisted, but I feel sure that if the continuous effect of wet could be avoided we should hear less of these cases of so-called frost-bite.

Mr. Swan in his interesting paper showed clearly that the conditions called "frost-bite" were not always exactly similar, making good his plea that they should receive close attention and further discussion both by pathologists and clinicians.

BRITISH COLUMBIA AND THE WAR.

Our Victoria, B.C., Correspondent writes:—"The recruits coming forward in Vancouver Island are so numerous that selection is easy. For example, none with false teeth are accepted for service in Europe. On the whole the men of the 30th Canadian battalion, which was the last to leave for the front, are taller than English soldiers used to be, though their chest measure is not so

large in proportion. The 30th battalion is made up of companies from all over the province of British Columbia, sent to train at Victoria on account of its open winter climate, rather milder than that of the Scilly Islands. Of the registered medical practitioners of British Columbia, 10 per cent. have already gone to the front or are under orders to go, and another 10 per cent. have volunteered and are waiting orders."

THE BRITISH RED CROSS SOCIETY.—The following is a summary of the work for the week ending March 13th, 1915:—

The number of auxiliary home Red Cross hospitals accepted by the War Office to date is 816, containing beds for 22,724, including 400 beds accepted during the past week. A number of Red Cross voluntary aid detachments are being utilised in connexion with these hospitals.

At the British Red Cross Hospital, Netley, the urgent need of more accommodation for isolation purposes is being met by the immediate erection of two small isolation huts. The Irish Hospital is now in full working order. During the week the following cases have been isolated: Enteric fever, 5; tetanus, 1; scarlet fever, 1; diphtheria, 1. The numbers in hospital this week are the highest so far—viz., British Expeditionary Force, 564; Belgians, 3; British Red Cross, 2; total, 569.

The Joint War Committee of the British Red Cross Society and the Order of St. John despatched the following during the week to Boulogne: 10 ambulances, 2 touring cars, 1 lorry, and 1 motor cycle; to Dunkirk: 1 ambulance; to Cannes: 1 touring car; and 1 ambulance for use in England. In all, 1165 cases of stores were sent abroad during the week. 374 cases were despatched to refill the warehouse at Boulogne. 281 cases were sent to Calais. Of these, 132 were for equipment of the huts in the enteric hospitals at that place, and the balance were requisitions for the Sophie Berthelot Hospital. During the week an urgent demand arrived from Cairo for supplies for the Australian Contingent, and 420 cases were sent to Egypt in an Admiralty transport. These cases were entirely drawn from the gifts made to the British Red Cross Society by the Commonwealth of Australia.

In addition to the stores above mentioned, 90 cases were distributed between Rouen, Paris, Fécamp, La Panne, and Dunkirk, and 111 hospitals in this country were supplied with 225 cases of stores of different kinds during the past week.

Ten motor ambulance kitchens have been completed for the front to minister to the wounded before they reach the hospital base. These vehicles have been designed to avoid as much as possible rattling, spilling, and breakage. Urns, bowls, and cooking utensils have all their allotted niches, while there is a gross of enamelled mugs distributed in wire trays convenient for carrying to the wounded. At the further end of each kitchen is the boiler for hot water with deep cooking "dixies" for making oxo, stews, cocoa, porridge, and so forth, while there are also a gas ring, a sink, and a serving hatch. The kitchens already in use at the front have been very much appreciated. According to the instructions issued by the British Red Cross Society the stores in the ambulance kitchen are to be used only for the wounded, but the cook in charge may cook army rations for the chauffeurs and orderlies attached to the ambulance unit. The stores include milk, tea, oatmeal, mutton (broth), coffee, and oxo.

Considerable outcry has arisen over the fact that war salaries of the British Red Cross nurses have been reduced from £2 2s. to £1 1s. a week. We are informed, however, that the explanation is a very simple one. When the war began the Order of St. John of Jerusalem was paying its nurses £1 a week, while those of the Society of the Red Cross were being paid 2 guineas a week. The joint committee appointed to coördinate the work of the two bodies called on a committee of ladies who had been nurses or hospital matrons to consider the matter and advise thereon. These ladies pointed out that the ordinary pay of a hospital nurse, an Army Medical Department nurse, and a territorial nurse is £40 a year, so it was decided that £1 1s. a week, or £54 12s. a year, as against £40 in the other cases, should be adopted for both the Order and the Society. Many

trained nurses are coming forward to accept these posts on the terms offered, being anxious to make personal and financial sacrifices, as doctors, business men, and others have done who have given up much to accept commissions in the Royal Army Medical Corps or other regiments, and even to serve in the ranks.

A MEDICAL OFFICER AT TRÉPORT.—We are enabled by the courtesy of a correspondent to publish some interesting extracts from a letter received from one who is at present serving in hospital at Le Tréport:—"Since I came out on August 14th I have seen much. We first went to Rouen, but after a fortnight had to leave hurriedly as the Uhlans were 20 miles away and the Taubes hovering ominously overhead. We read of our retreat being masterly. From Rouen we went to St. Nazaire, where we stayed for three months. Our work was very hard, as we had to bear the brunt of the battle of the Marne. Night and day we worked for many days. The operating theatre at one time was not disengaged a minute for four days. I shall never forget it. From St. Nazaire we returned to Rouen, and now we are at Le Tréport, about 30 miles south of Abbeville. It is an admirable hospital: all sorts of people have visited us, among them Lord Gladstone, Cardinal Bourne, and the Chief Rabbi. The consultants, Moynihan, Bradford, Makins, and Gray, have frequently been here. The character of the work has changed considerably. During the winter months medical cases have predominated. Wounds are not so severe or so numerous, owing to the entrenched positions which have been established. Tetanus is now rare since the commencement of injection of serum on the field; all wounded soldiers receive an injection of serum within 24 hours of being wounded. Cases of so-called frost-bite are less numerous; now that spring is upon us they will disappear. Everywhere great preparations are being made for the spring campaign. An advance must be made soon, and the casualties must be enormous. Rumours of all sorts fly around. Some expect the war to be over in August; others say it will last over another winter. Food seems to be running short in Germany; the spectre of starvation, together with lack of munitions, may end matters.

We are engaged in a fight for existence on an unprecedented scale. What a blow this war has been for pacifists who attempt to show that war is dying out. Here human passion is displayed in all its brutality, and science and culture have been called in to make it more awful. The dream of the time when battle flags shall be furled in the brotherhood of man and the federation of the world is like a will-o'-the-wisp to a wearied and tired traveller."

VACANCIES FOR MEDICAL OFFICERS.—We are informed that there are vacancies for medical officers in the three Field Ambulances of the Home Counties Division (T.F.) at present quartered at Windsor. Officers are required for the 1st, 2nd, and 3rd Field Ambulances. The chances of early service abroad appear to be more certain than as a regimental medical officer with any infantry unit. Information as to pay, allowances, and other conditions can be obtained by addressing the officer commanding the 1st Home Counties Field Ambulance, R.A.M.C. (T.F.), Windsor.—Six medical officers are required also at once for commissions as lieutenants in the 1st North Midland Field Ambulance. Apply to Officer Commanding, R.A.M.C. Dépôt, 91, Siddals-road, Derby.

ROYAL HANTS COUNTY HOSPITAL AND THE WAR.—The annual report states that the number of in-patients treated during the year was 1691; the increase over those of last year was 333 and the increase in operations was 247. The institution has placed 30 beds at the disposal of the War Office, and 70 Belgian sick and wounded soldiers, 22 wounded soldiers from the Expeditionary Force, and 155 sick soldiers from the camps around Winchester have been treated in the hospital. 118 soldiers have been X-rayed. The cost per patient has increased from 3s. 6d. to 4s. 1d. per diem, but the average stay of 27 days in 1913 has been reduced to 22 in 1914.

CHARING CROSS HOSPITAL.—At the annual court of governors on March 11th it was announced that the five wards closed until recently for lack of funds had been practically full of soldiers since September. The hospital accommodation was increased from 150 to 260 beds.

ARRIVAL OF WOUNDED IN EDINBURGH.—A hospital train with wounded arrived at the Caledonian station at midnight on March 11th from Southampton. There were altogether 100 cases. A number had come direct from the front, while others had come from hospitals. They included a few who had been the victims of frost-bite, but the great majority of the men were suffering from wounds. While there were members of other regiments, a good many belonged to Scottish battalions. Fifty of the cases were sent to Craigleith, 30 to Dalmeny, and 20 to the Deaconess Hospital. The removal of the men was carried out by members of the Red Cross Society.

A LECTURE ON THE WAR.—A popular lecture on the War and the Wounded, 1870-71, 1914-15 (announced in our last issue), was given at the Royal Society of Arts on March 12th by Mr. Adolphe Smith. Sir William J. Collins presided. Mr. Smith, in dealing with his personal experiences in the two wars, urged that it was in the sequence of events that history gave its most useful lessons. To-day, he said, the Allies were marching to victory because they were not unmindful of past experience. France was not beaten by the Germans in 1870-71, because the Germans never had to fight the French nation. They routed the partisans of the French empire at Sedan and starved republican Paris into surrender, that was all. To-day the Germans were confronted by a united French nation and had learnt the difference to their cost. The lecturer gave anecdotes of the siege and the war by starvation. Among the 2,000,000 civilians besieged in Paris the death-rate, for want of proper food, rose from 900 to 6000 per week. This was what we might now be enduring in London, he said, if the Fleet failed to safeguard our supplies. The danger of pestilence, which so frequently followed close on the wake of war, still remained. Fortunately we were now better armed against its horrors. Pasteur and Lister had given us antiseptic surgery, and Parkes, Edwin Chadwick, Emile Trélat, and other sanitary reformers had taught us how to battle with epidemic diseases. In spite of the greater risk and difficulties resulting from a much more extensive battlefield, there was to-day a smaller mortality from wounds and, so far, a wonderful immunity from contagious diseases. The lecturer illustrated his comparison between the two wars by lantern slides and demonstrated by photographs of actual incidents of transport and of hospitals the extraordinary development of voluntary aid and scientific treatment in the care of the sick and wounded that has recently taken place. But, he said, the struggle was not over. Cholera prevailed extensively in the Austrian army and there was typhoid fever among the Belgian troops. The former disease often travelled on the heels of the latter, so that every nerve must be strained to ensure perfect sanitation. The fighting was not all conducted on the field of battle or in the trenches. Even the feeblest might help in the national defence, for here in England, as in the plains of Flanders, work and money were wanted. England expected not merely every sailor and soldier, but every man and every woman to do his or her duty.

HOPETOUN HOUSE AUXILIARY HOSPITAL.—The ballroom wing of Hopetoun House has been fitted up by Lord Linlithgow as an auxiliary Red Cross hospital. Forty-one beds have been provided, and 32 patients are under treatment. Miss Oliphant, sister of the minister of Abercorn, is acting as matron, and a staff of 11 nurses is drawn from the Voluntary Aid Detachment of the Red Cross Society. Little required to be done in order to adapt the spacious ballroom to its present purpose, the erection of a kitchen and offices was necessary. The patients have ample scope for taking air and exercise in the beautiful grounds. Drafts arrive regularly at the hospital from the first-line hospitals. The patients under treatment at present mostly suffer from bullet wounds in the limbs and from frost-bite.

DEATH OF DR. E. N. MACBEAN ROSS.—Elizabeth Ness MacBean Ross, M.B., B.Ch. Glasg., of Nairn, N.B., died in February from typhus fever after 13 days illness, at Kragnevat, Serbia, where she was in charge of the typhus wards. Her funeral, which was according to the Greek rite, supplemented by an English service at the graveside by the British Military Attaché, Colonel Harrison, was attended by a large number of Serbian nurses and officers.

RED CROSS GIFTS FROM INDIA.—The donors of Red Cross gifts which the Indian St. John Ambulance Association has been despatching to the front since August last may judge by the following extracts from letters from the front how much they are appreciated. An officer serving in a general hospital in the Canal Defence Force, Egypt, writes: "I received for the use of the above hospital some boxes of Red Cross gifts from Simla. I am writing to convey to the donors through you, my great appreciation of their kindness and generosity; the gifts are most welcome and of great use and are thoroughly enjoyed by the sick." The following letter from Basra is written by an administrative medical officer: "I sent you a cable to-day asking for pipes and tobacco for British, and cigarettes *bidie* (Bombay Indian cigarettes) and narrow cotton-wool or coir mattresses for Indian troops. The want of a smoke is much felt and we have seemingly used up all the local tobacco. The cigarettes and tobacco in the Red Cross gift boxes were a great standby. It is a platitude to state that the gift boxes sent for both British and Indian troops were greatly appreciated. They filled a huge hiatus and brought great comfort to many a suffering wounded man. Every article has had its use. Send more warm flannel clothes, pyjama suits, socks, Balaclava caps, and flannel shirts. The dressing gowns were an immense boon. The nights are now cold and frosty and most of the sick and wounded are in tents. Indian quilts are also a great acquisition."

MEDICAL SURVIVORS FROM H.M.S. "BAYANO."—We congratulate Surgeon Kenneth H. Hole, R.N., and Probationary Surgeon Richard Batson, R.N.R., on being among the fortunate few rescued from the *Bayano*, recently torpedoed while on patrol duty.

A NEW RED CROSS HOSPITAL IN CO. DUBLIN.—Last week a Red Cross hospital was opened at Corrig Castle, Kingstown, kindly lent by the owners, Lord Longford and Lord De Vesci. There is provision for 30 beds, of which 16 are for officers. An operating-room and an X ray room have been fitted, and a competent honorary visiting staff has accepted office. The hospital is now ready to receive patients.

SOLDIERS' AND SAILORS' DENTAL AID FUND.—A public meeting will be held in aid of this fund at the Hampstead town hall on Thursday, March 25th, at 3 for 3.30 P.M., under the patronage of H.I.H. the Grand Duke Michael. The chair will be taken by the Mayor of Hampstead. Among the speakers will be Mrs. Parker (Lord Kitchener's sister) and Mr. Ben Webster. Mr. Henry Ainley will recite. Admission free. A few reserved seats at 2s. 6d., including tea, can be obtained from the honorary secretary, 36, Leicester-square, W.C.

A NEW GLASGOW WAR HOSPITAL.—The corporation of Glasgow has granted the use of its art galleries at Kelvingrove to the military authorities as a hospital for wounded soldiers. The galleries will accommodate 520 beds when all the art treasures have been removed.

THE WOUNDED AT EPSOM.—It is gratifying to learn that an agreement has been come to under which there will be no disturbance whatever of the war hospital situated in the grand stand annexe at Epsom.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council on March 11th Licences to practise dentistry were conferred upon the following 20 candidates (including one woman) who have passed the requisite examinations and complied with the by-laws:—

Philip Eric Bernhard, Charles Alfred Ernest Cook, and Trafford Dudley Corke, Guy's Hospital; Arnold Court, Birmingham University; Frank Briggs Cullen, Middlesex and Royal Dental Hospitals; Clifford Cedric Dixon, Leeds University; John Langley Garrard, Guy's Hospital; Gawin Herdman, Liverpool University; Joseph James Sterling Hill, Guy's Hospital; Arthur James Hornblow, Middlesex and Royal Dental Hospitals; Alan Lawrence Miller, Birmingham University; Wallis John Milton, Bristol University and Royal Dental Hospital; Owen Colville Morphy, Middlesex and Royal Dental Hospitals; Philip Thomas Pearce, Guy's Hospital;

Eric Vincent Pollitt, Manchester University; Frank Edwin Rudd, Guy's Hospital; Leonard Smith, Birmingham University; Percival Washington Symons, Middlesex and Royal Dental Hospitals; Marjorie Jane White, Bristol University; and John Clark Yeoman, Birmingham University.

The Council also conferred the Diploma of Fellow upon Mr. Shamrao Ramrao Moolgavkar, who has now complied with the by-laws of the College.

UNIVERSITY OF BRISTOL.—At the second examination for the degrees of M.B., Ch.B., the following candidates passed:—

John D'Arcy Champney and Evelyn Bessie Salter.

UNIVERSITY OF OXFORD.—The following appointments of university lecturers have been made: Mr. Horace M. Vernon, D.M., Fellow of Magdalen College, as University Lecturer in Chemical Physiology for four years from Jan. 1, 1915; and Mr. John W. Jenkinson, M.A., D.Sc., Exeter College, as University Lecturer in Comparative and Experimental Embryology, for five years from Oct. 10th, 1915.

ROYAL SOCIETY OF MEDICINE.—The Council Club will dine at the Café Royal, Regent-street, W., on Wednesday, March 24th, at 7.30 P.M. Members who desire to be present are requested to notify Mr. J. Y. W. MacAlister, the secretary, not later than Monday, March 22nd.

HUNTERIAN SOCIETY.—At the annual discussion on March 24th next, at 9 P.M., at the Barbers' Hall, Monkwell-street, E.C., Dr. T. B. Hyslop will introduce the subject of Recent Developments in Psychotherapeutics. All members of the medical profession are invited.

A NEW CORONER'S COURT.—The borough of Southwark is to be congratulated on the provision of a new coroner's court in St. George's churchyard, where an inquest was held for the first time on March 2nd. The coroner (Dr. F. J. Waldo), medical men attending the inquests, and juries will appreciate the spacious court with its sound hygienic fittings and facilities for viewing the body without any risk of infection or unpleasantness. A Herscher's formalin preserving chamber, in which a body may be preserved for almost any length of time, is connected with the court, and the post-mortem room is fitted with the most approved appliances, including a turning table and an apparatus for washing viscera.

BRISTOL GENERAL HOSPITAL.—The annual meeting of the subscribers of the Bristol General Hospital was held on March 8th under the presidency to the Lord Mayor. The report stated that during 1914 the in-patients numbered 3271, being 215 in excess of 1913. The out-patients amounted to 34,182, an increase of 257 compared with the previous year. 618 patients were sent to the Jubilee Convalescent Home, Durdham Downs. The financial statement showed that the ordinary income was £11,799; the legacies amounted to £2858. The total ordinary expenditure was £17,593.

HOSPITAL FOR CRIPPLED CHILDREN, ALTON.—A new ward for crippled children has been opened at Sir William Treloar's Hospital for Cripples, Alton. Queen Alexandra telegraphed a congratulatory message, and Sir William Treloar presented to Frederick Barber and Doris Huntley, whose fathers are serving respectively in the Coldstream Guards and the Royal Scots Fusiliers, Queen Alexandra's medals for the children of soldiers and sailors.

ANCOATS HOSPITAL, MANCHESTER.—Through the generosity of a lady, who desires to remain anonymous, a complete electrocardiographic installation has been supplied to the hospital. Demonstrations of the practical use of this instrument will be given on Thursday and Friday, March 25th and 26th, at 4.30 P.M.

THE WELLCOME HISTORICAL MEDICAL MUSEUM.—The Wellcome Historical Medical Museum will be closed for cleaning from April 1st to April 19th inclusive.

THE AMERICAN ASSOCIATION OF IMMUNOLOGISTS will hold its annual meeting at Washington, D.C., on May 10th, under the presidency of Dr. Gerald B. Webb, of Colorado Springs, Colo. The secretary is Dr. Martin J. Synnott, of Montclair, N.J.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Health of the Army.

In the course of his speech in the House of Lords on Monday, March 15th, Lord KITCHENER made a brief reference to the health of the army at the front. "The health of the troops," he said, "has been remarkably good, and their freedom from enteric fever and from the usual diseases incidental to field operations is a striking testimony to the value of inoculation and to the advice and skill of the Royal Army Medical Corps and its auxiliary organisations."

Naval Medical (Compassionate Fund) Act.

Amongst the Acts which received the Royal Assent on Tuesday, March 16th, was the Naval Medical (Compassionate Fund) Act.

The Easter Holidays.

Both Houses of Parliament have adjourned for the Easter Recess. They will reassemble on April 14th.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 10TH.

The Making of Tinctures in Hospitals.

Mr. BRIDGEMAN asked the Chancellor of the Exchequer whether he would consider the desirability of providing in the Finance Bill for the supply of duty-free rectified spirit to hospitals for the making of tinctures under similar restrictions to those which regulated the supply of absolute alcohol free of duty for purposes of research in clinical laboratories and colleges.—Mr. LLOYD GEORGE replied: The general question of the use of spirit is under consideration, but I am afraid that it would not be possible to grant this particular exemption.

Mr. BRIDGEMAN: Is the right honourable gentleman aware that the London Hospital alone has spent £256 on tinctures of this kind, of which £229 is duty, and could he not, at any rate, make an exception in favour of tinctures and solutions of iodine? I think it will be easier to do that.—Mr. LLOYD GEORGE: I could supply the honourable gentleman with the reasons given to me by the Customs as to the difficulty of making a discrimination. I shall hand the paper over to him.

Treatment of Nervous Breakdown in London.

Mr. W. THORNE asked the President of the Local Government Board whether his attention had been drawn to the need at this crisis for the treatment, apart from lunacy, of recent and uncertifiable cases of nervous breakdown; and whether, in that case, it was still imperative that any application from the London County Council or other county councils for powers to provide such treatment must be delayed till after an expert inquiry, seeing that borough councils now possessed these powers.—Mr. HERBERT SAMUEL answered: I would refer the honourable Member to previous replies. As regards the powers which the London County Council are seeking in their General Powers Bill, it will be for the committee before which it comes to decide whether the particular power should be given.

Asylums Taken Over by the Military.

Mr. CHARLES DUNCAN asked the Home Secretary whether he could state the position of the staffs of those asylums taken over by the military authorities; whether the Government proposed to utilise the services of the existing staffs; whether their continuity of service for the purposes of superannuation would be safeguarded; and whether their pay and prospects would remain not less favourable than those at present enjoyed in the services of the local authorities concerned.—Mr. McKENNA said in reply: The answer to all the points in the question is in the affirmative. I am advised that as the asylums will during their use as military hospitals continue to be for legal purposes asylums, and the officers will remain in the service and pay of the asylum authority, the Asylum Officers' Superannuation Act, 1909, will continue to apply to the officers, and their service for pension purposes will not be broken.

Antityphoid Inoculation.

Mr. CHANCELLOR asked the Under Secretary for War a series of questions in regard to the treatment of certain soldiers who had not been inoculated.—Mr. TENNANT wrote in reply: I am making inquiries into these cases, as it is impossible to obtain full details at such short notice. I understand the position generally in the cases referred to to be that men are not being punished for not submitting to inoculation, but as only the inoculated men are being sent to the front those uninoculated are not given the privilege leave allowed to men under orders for abroad.

Epsom Stand as a Hospital.

Mr. WHITEHOUSE asked the Under Secretary for War whether the agreement with the authorities of the Epsom stand, now being used as a hospital, necessitated the removal

of a number of the wounded from that part of the stand which was to be reoccupied by the owners of the stand; the number of wounded who would be so disturbed; and whether they were being removed to other rooms in the stand or sent to other hospitals.—Mr. TENNANT furnished the following written answer: No removal of patients is involved, as before the Spring Meeting those occupying the third floor will have been discharged on sick furlough. Patients are not accommodated on the ground floor or in the basement, the remaining portions of the Grand Stand affected by the agreement. The hospital, which is now used for transfers from Woolwich and not for direct admissions from overseas, will be filled again after the Spring Meeting.

Dental Treatment for Recruits.

Sir WILLIAM BULL asked the Under Secretary for War whether an official intimation had reached Nottingham that the War Office had sanctioned a change regarding recruits and defective teeth; whether men would now be allowed to be attested if otherwise fit and subject to their consenting to undergo dental treatment; and, if so, whether it was proposed to extend such official orders to other recruiting centres.—Mr. TENNANT (in a written answer) replied: Instructions have been issued to all commands that recruits found physically fit in every respect except on account of insufficient teeth may be passed by a medical examiner of recruits as "fit, subject to dental treatment." Such men, if willing to undergo dental treatment, may be attested and dispatched to the depot, final approval being deferred until they are pronounced to be in all respects fit. The necessary dental treatment will be carried out as soon as possible after the men's arrival at the depot.

Dentists in the Field.

Sir CLEMENT KINLOCH-COOKE asked the Under Secretary for War whether he was aware that dentists were attached to the New Zealand Expeditionary Force, and would he consider the possibility of attaching dentists to the different units of the new army.—Mr. TENNANT wrote in reply: Yes, I am aware that dentists are attached to the New Zealand Expeditionary Force. Dentists and dental mechanics with full outfits, instruments, apparatus, and material were some months ago supplied to the British Expeditionary Force. Dentists have already been appointed at the large stations in the United Kingdom, and more appointments will be made, if required, as soon as the instruments, &c., are available from the manufacturers.

Medical Stores at Military Encampments.

Mr. WALTER GUINNESS asked the Under Secretary for War whether he was aware that in many of the new hut encampments there was no accommodation for keeping medical stores and instruments or for the officers in medical charge to see the sick, who in many cases had to walk considerable distances in consequence; and whether steps would be taken to supply huts for that purpose.—Mr. TENNANT wrote in reply: At the larger hatted camps there are hut hospitals with suitable accommodation for examining the sick and keeping medical stores. At some others there are medical examination rooms specially built, and generally where the medical authorities have asked for these to be provided they have been built. In some camps where special huts have not been built for this purpose and where the troops are in occupation, it is possible to arrange for seeing the sick in some existing huts which are to spare. If it is found that spare huts are not available medical inspection rooms can be built as in the cases alluded to.

THURSDAY, MARCH 11TH.

Epsom Stand as a Hospital.

Replying to Mr. WHITEHOUSE, Mr. TENNANT said: I understand that an agreement has now been come to under which none of the accommodation at the Epsom Grand Stand which has been used as a hospital will have to be vacated in connexion with the spring meeting. This very satisfactory arrangement reflects credit upon those concerned.

Supplies of Opium.

Sir J. D. REES asked the Under Secretary for India whether there was at present a serious deficiency in the supply of opium for medicinal purposes; whether prices had greatly risen; and to what extent the deficiency in stocks and the rise in prices was due to the Government policy of destroying the opium trade.—Mr. CHARLES ROBERTS answered: I am informed that at present the market for opium for medicinal purposes in this country and in the United States is well supplied and that prices are tending to fall. Opium for these purposes has previously been drawn from the Levant and from Persia, and the supply is quite independent of the Indian Government's opium policy.

Dope Poisoning.

Mr. ROWLANDS asked the Under Secretary for the Home Department whether his attention had been called to the case of a young girl working on aeroplanes being killed by dope poisoning on Feb. 28th; whether this was the second death this year at the Crayford works; whether there had

been other cases in other parts of the country; whether it was admitted in the evidence at the inquest on March 3rd that the system of ventilation required by the Home Office to prevent dope poisoning, which was supposed to be perfect, had failed; whether the Home Office was still thoroughly satisfied that the provision of effective means of ventilation was a sufficient precaution, and what were those means; or whether any further steps had been taken to ensure the absolute safety of the health and lives of the young women employed on varnishing with dope.—Mr. CECIL HARMSWORTH replied: I am aware of this case, but I am advised that the circumstances attending it do not throw doubt upon the efficiency of the means which have recently been taken on the recommendation of the Home Office to prevent dope poisoning. Poisoning from dope is gradual, and in the case in question the mischief must have arisen before the installation of the new system of ventilation, as the ventilation was not at work till the latter half of January, and the girl who had been employed on this work since October left on Feb. 3rd. I am informed that it is not correct that any admission was made at the inquest that the system of ventilation had failed. The arrangements at the Crayford works which provide for the removal of the fumes at the point of origin have been carefully inspected by the expert advisers at the department and have been reported by them to be quite satisfactory.

Mr. ROWLANDS: I would like to know whether the medical authorities of the Home Office are satisfied now, as they were a month ago, that this ventilation system is thoroughly efficient, and whether they will take the precaution of again examining the girls as they did in December, when they found 43 girls affected by the fumes?—Mr. CECIL HARMSWORTH: Yes. I believe the medical officers of the department are perfectly satisfied with the system, but if my honourable friend would like another inspection made I will make representations to the proper authorities.

Mr. ROWLANDS: I should like it.

Soldiers' Nerve Strain.

Lord ROBERT CECIL asked the Under Secretary for War whether the War Office would give an undertaking that in future uncertifiable soldiers invalided through nerve strain would not be placed under asylum administration or in charge of officials connected with lunacy, and that, in the event of their becoming certifiable, such soldiers as were already interned in the State institution at Moss Side, near Liverpool, or in similar institutions elsewhere would not be certified except by independent physicians unconnected with any lunacy staff or with the Board of Control.—Mr. TENNANT wrote: No case of nerve strain is or will be placed under asylum administration. Cases in military hospitals, if transferred on discharge as certifiable lunatics to county asylums, will come before a board of military medical officers and are certified under the Lunacy Act.

MONDAY, MARCH 15TH.

Duty-free Alcohol in Laboratories.

Replying to Mr. BOLAND, Mr. BECK (on behalf of the Secretary to the Treasury) said: It is already the practice to allow public institutions to use duty-free alcohol in their laboratories for research purposes.

Prevention of Spotted Fever.

Mr. CHARLES BATHURST asked the Under Secretary for War whether, in view of the existence and possible spread of spotted fever in various English camps and garrison towns, he would take steps to have published in garrison and regimental orders, for the information of all military units, the warning lately officially expressed by Dr. Newsholme, medical officer to the Local Government Board, to the effect that cerebro-spinal fever was generally associated with overcrowding, insufficient ventilation, and uncleanness.—Mr. TENNANT answered: Special instructions have already been issued to all commands in connexion with this disease to ensure that the troops are not overcrowded or accommodated in buildings or houses which are insanitary, and to consult with the medical officers of health and the military sanitary officers as to the necessary measures to be taken.

Antityphoid Vaccine.

Answering Mr. JOWETT, Mr. H. BAKER (Financial Secretary to the War Office) said: The antityphoid vaccine used in the army is made in the laboratory of the Royal Army Medical College, but since the outbreak of the war the Inoculation Department of St. Mary's Hospital and the Lister Institute have provided the Army Medical Department with a large quantity of this vaccine at cost price, as the output from the College was insufficient to supply the increased number of troops. The cost of production of army vaccine in the laboratory of the Royal Army Medical College is estimated to be 1½d. per double dose per man.

Inoculation against Typhoid.

Mr. BAKER informed Mr. JOWETT that no fees nor other remuneration beyond the salaries of army medical officers were paid for inoculation or vaccination against typhoid.

Grants for Sanatoria.

Sir RYLAND ADKINS asked the Chancellor of the Exchequer whether the Treasury would sanction during the war any advances of capital or loans for institutional treatment under the National Insurance Acts or the Mental Deficiency Act.—Mr. LLOYD GEORGE wrote in reply: Capital grants for sanatoria will continue to be made where necessary and, subject to the same proviso, local authorities will not be prohibited from borrowing for the same purpose. As regards loans under the Mental Deficiency Act, I do not think that capital expenditure for this purpose is desirable at the present time in the absence of very special considerations.

Medical Service with the Army.

Several topics relating to the medical service with the army were referred to during the debate on the motion for the adjournment for the Easter Recess.

Mr. WALTER GUINNESS said that in many cases medical officers in the Territorial Force had come out, at disastrous results to their professional positions and prospects. In many cases they had only two days' notice. At that time it was absolutely impossible to find a locum-tenent. Cases had been brought to his notice where medical men came away from practices which they had built up for themselves by years of painstaking attention, and they had to leave those practices without anyone to look after them for six or eight weeks. These medical men who had probably reached comfortable positions financially suddenly found their income reduced to 14s. a day. That income was, no doubt, reasonable enough for the annual training, but they felt it was most unjust that while they were receiving 14s. a day, doctors who were now joining the New Armies with the same rank of lieutenant were receiving 24s. a day and allowances in addition. The best pay was being given to those who had made the least sacrifices. In many cases doctors who joined the New Armies were only just qualified. He was informed that a larger proportion of candidates were being passed than in times of peace, and a large number of those were joining the New Armies. Even in the case of men who had given up practices, their sacrifices had been considerably less than the Territorials, because the former had in many cases taken four or five months to arrange about a locum-tenent and to put their affairs in order. He did not say that it was possible or reasonable that the Government should pay the regular Royal Army Medical Corps officer in the same way as an officer in the same class in the New Army. He thought that the line had been drawn in the wrong place. The War Office ought to have drawn it not between one class of casual medical officer, who would go back to civilian employment, and another, but between the permanent army doctor and the temporary one. Pay which was suitable enough for a permanent army doctor was quite insufficient for a man who was much older and probably had got a family to keep and who had made a very large sacrifice of his civilian practice. When the temporary medical officer returned to civil life he found his practice gone, and he would probably have to work right up again from the beginning. He knew what the War Office answer was. It was that the Territorial medical officers contracted during peace time on certain terms, and it was only reasonable that they should carry out their bond, and that the War Office had to go out in the open market and employ men at what their services would fetch. That was not a fair answer. It was not true that the Territorial medical officer was carrying out the contract which he undertook in time of peace. It was not so in two respects. First of all, in times of peace he only made himself liable for service at home. The vast majority of Territorial medical officers—the only ones for whom he was pleading—had accepted the obligation to serve abroad. Again, these men joined in a particular unit. They were distinctly given to understand that though they were members of the Royal Army Medical Corps (Territorial Force) they would be definitely attached throughout the whole period of their service to a selected unit. A few weeks ago they received a circular stating that it was impossible in view of the dearth of officers to retain that system which had been maintained in the Territorial Force prior to the outbreak of hostilities, so that in two respects these medical men for whom he was pleading were in an absolutely different position from that which was contemplated when they joined the Territorial Force.

Mr. PIKE PEASE said that it seemed to him if it was possible to find an alternative to the rum ration, that it would be wise for the War Office to give it to the troops.

Mr. TENNANT (Under Secretary for War) said that the honourable Member for Darlington (Mr. Pike Pease) had been good enough to make suggestions to him by which it was hoped that an alternative might be found to the rations for that large and growing body of men who objected on principle to taking alcohol to be supplied as an alternative to rum in the trenches. He could assure the honourable Member that he would bring to the notice of the Director of Medical Stores and the Director of Supplies the suggestion he had made, and he dared to say that if they all tried

together they might find something which it would be suitable and possible to provide to that very deserving class of total abstainers.

Mr. RONALD MCNEILL said that there were a number of retired medical officers who at the time of mobilisation were in charge of depôts and who on mobilisation were recalled to the service. By a certain rule in the Regulations of the Army officers who had retired and were recalled to the service at a time of emergency were allowed a grant of £100 towards their outfit. At the time of the outbreak of the war the Army Council issued various Orders to certain commands and advertised this grant to which officers were entitled to. Medical officers were, if he was correctly informed, under no obligation in regard to the providing of uniform until a comparatively short time before the outbreak of the war. He thought that it was in May of last year that they were first called upon to provide themselves with uniform, and when the war broke out and the various Orders were made known there was nothing to lead the medical officers to know that they would be treated differently from other officers of similar rank and position. To begin with, their pay was much smaller. They had much less means for providing themselves with uniform, and they naturally expected equal treatment. A few weeks after the mobilisation Order they were suddenly told that they were not to expect this grant, although other officers of the Regular Forces were to receive £100 for providing uniform. Medical officers were not to be given anything towards the provision of that. That was a grievance, and they felt, he thought, rather keenly that they were in a worse position than brother officers of the fighting line. They thought that they ought to receive the same consideration.

Mr. H. BAKER (Financial Secretary to the War Office) said that it had been pointed out that it appeared that a lieutenant in the Territorial Force or the Royal Army Medical Corps received 14s. a day, whereas a person of the same rank performing the same duties in the New Army received 24s., apparently a difference of 10s., which did seem very considerable. The honourable Member (Mr. Guinness) omitted altogether the question of allowances to which these two types were respectively entitled. Whereas the man in the Territorial Force with his 14s. a day was entitled to allowances which might bring him up to 21s. 9d. as a maximum, the civilian who came into the New Army could never in any case get a greater sum than 25s. 9d. The difference, therefore, instead of being so great as 10s., was, in fact, 4s. There was still a difference. He agreed that it was not very easy to deal with this and other cases. What were the authorities to do when they found the supply of a particular kind of soldier was falling off? In order to increase the supply they had to raise the price in the market. What were they to do when those who originally entered on the lower basis found that their position, though it was satisfactory before, was now not so satisfactory compared with that of the later recruits? The authorities must either leave them as they were or they might level up. Levelling up was a big business if it were set about in that way. It had hitherto been the practice to leave people as they were. That was done in the South African War. It was not then thought necessary that the first comers should be raised to the higher rates paid to the later comers. In cases it might seem hard to a man that he should be doing precisely similar work to the man beside him for a lower rate of pay. But when once the levelling-up process began it might become endless. If they began to put up rates they could not confine the process to a small section. An increase must apply to all who had gone before. In putting it thus he hoped that he would not be thought to depreciate in any way the very great sacrifices which honourable Members had described and which were being borne by the medical profession on behalf of the country. There was no doubt that doctors all over the country had given up valuable practices and had given from time to time their energy and service to the country.

Mr. BRIDGEMAN: When was the salary for doctors raised? My impression is that it was raised immediately after the war began.—Mr. BAKER: It was when the formation of the New Army began.

Mr. BRIDGEMAN: Then how did you know that a sufficient number of doctors would not be forthcoming at the old rate? —Mr. BAKER: The higher rate was, of course, based on information in the possession of the Surgeon-General of the Army Medical Service, who is in close touch with the profession. He knew the enormous number that would be required as well as the number likely to be available. Very careful records are kept in peace time of the doctors who may be expected to serve, and I do not doubt that it was on these statistics that the decision was come to that if the necessary number of doctors was to be obtained the rate of pay must be slightly increased.

Mr. MCNEILL: Will the honourable gentleman say a word about the exclusion of medical officers from the kit grant? —Mr. BAKER: It did not appear to me to be quite in accordance with the actual practice, and if the honourable Member

desires I will communicate with him by letter. I will conclude by saying that in all these cases of men working side by side on differential rates of pay I hope the honourable Member will not suppose it is through any indifference to the merits of this class or through any failure to recognise the great sacrifices which they are making that the present principle is observed.

TUESDAY, MARCH 16TH.

Indian Assistant Surgeons at the Front.

Mr. O'GRADY asked the Under Secretary of State for India whether he was aware that there were a number of Indians acting as assistant surgeons at the front and that these officers had a large and continuous military medical experience, including that of the present war; and whether, in view of these facts and the consequent shortage of medical men who must obtain their degrees in Great Britain before they could obtain the rank of commissioned officer, steps would be taken to promote to commissioned rank the assistant surgeons who had obtained certificates through examinations in India.—Mr. CHARLES ROBERTS replied: Vacancies occurring in the commissioned ranks of the Indian Medical Service are being made good by the grant of temporary commissions to medical men, Indians and others, having a professional qualification that is registrable in the United Kingdom. It is not considered desirable to lower the standard of admission.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

- BLAKE, PAUL, L.R.C.P. & S. Irel., has been appointed Medical Officer of the Kilmeague and Robertstown Dispensary District by the Naas Board of Guardians.
- DEAN, HENRY ROY, M.D., F.R.C.P. Lond., has been appointed to the Chair of Pathology and Pathological Anatomy in the Sheffield University.
- DOYLE, F.W., M.B., B.Ch. N.U.I., has been appointed Assistant Master of the National Maternity Hospital, Dublin.
- FOWLER, S.C., M.B., C.M. Edin., has been appointed Chairman of the Midlothian Local Medical Committee in connexion with the National Insurance Act.
- MACDONALD, D. M., M.D., F.R.C.P. Edin., has been appointed Visiting Physician to the Manchester and Salford Convalescent Home, Arnside, Westmorland.
- MCVITTIE, A. C., M.B., B.Ch. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Lerwick District of the county of Shetland.
- METCALFE, BRIAN BENTLEY, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the St. Cleer, St. Pinnock, and St. Neot Districts by the Liskeard (Cornwall) Board of Guardians.
- MILLER, WILLIAM ROBERT, M.D., B.Ch., B.A.O. Dub., has been appointed Medical Officer and Public Vaccinator for the Fifth District by the Penzance (Cornwall) Board of Guardians.
- NETTLE, WILLIAM, M.R.C.S., L.S.A., has been appointed Medical Officer for the St. Cleer, St. Pinnock, and St. Neot Districts by the Liskeard (Cornwall) Board of Guardians.
- RAWSON, WILLIAM F., F.R.C.S. Edin., L.R.C.P. Lond., has been appointed Surgeon to the Bradford Municipal Maternity Hospital.
- STEWART, W. P. A., M.B., Ch.B. Glas., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Tarbert District of the county of Argyll.
- WATSON, HENRY, M.B., Ch.B. Glas., has been appointed Medical Officer of the No. 2 Medical District of the Paisley Parish Council.
- WRIGHT, F. R. E., M.B. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Braunton District of the county of Devon.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

- ASHTON-UNDER-LYNE DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with residence, board, &c.
- BIRKENHEAD BOROUGH HOSPITAL.—Senior House Surgeon. Salary £120 per annum, with board and laundry. Also Junior House Surgeon. Salary £100 per annum, with board and laundry.
- BIRMINGHAM, CITY OF.—Female Assistant Medical Officer of Health for Infant Consultation work, &c. Salary £300 per annum.
- BIRMINGHAM, CITY MENTAL HOSPITAL, Winslow Green.—Assistant Medical Officer. Salary £250 per annum, with apartments, board, laundry, &c.
- BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, fire, lights, and attendance.
- BIRMINGHAM, QUEEN'S HOSPITAL.—Two House Physicians. Salary at rate of £80 per annum, with board, apartments, washing, and attendance.
- BOLTON INFIRMARY AND DISPENSARY.—Senior House Surgeon and Second House Surgeon. Salary £230 and £200 per annum respectively, with apartments, board, and attendance.

- BOOTLE BOROUGH HOSPITAL.—Senior and Junior House Surgeons. Salary £150 and £130 per annum respectively, with residence board, and laundry.
- BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL.—Three House Surgeons for six months. Salary £100 per annum, with board, lodging, and washing.
- BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.
- BRIGHTON, ROYAL SUSSEX COUNTY HOSPITAL.—Two Resident Medical Officers. Salaries £150 per annum, with apartments, board, laundry.
- BRISTOL GENERAL HOSPITAL.—First House Physician, Second House Physician, House Surgeon, and Casualty House Surgeon, also Resident Obstetric Officer, for six months. Salaries at rate of £150 per annum, with board, residence, &c.
- BRISTOL ROYAL INFIRMARY.—Three House Surgeons. Two House Physicians, and One Obstetric and Ophthalmic House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.
- BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £135 per annum, with residence, board, and washing.
- BURY INFIRMARY.—Junior House Surgeon. Salary £150 per annum, with board, residence, and washing.
- BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Physician for six months. Salary £100 per annum, with apartments, board, and laundry.
- CANTERBURY, KENT COUNTY ASYLUM, Chatham.—Third Junior Assistant Medical Officer. Salary £250 per annum, with quarters, board, washing, &c.
- CARLISLE, CUMBERLAND INFIRMARY.—House Physician for six months. Salary as arranged.
- CARLISLE, CUMBERLAND AND WESTMORLAND ASYLUM, Garlands.—Junior Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, and washing.
- CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.—Resident House Surgeon. Salary £50 per annum, with board and residence.
- CHESTERFIELD, BOROUGH OF.—Medical Officer of Health. Salary £500 per annum.
- DERBY, DERBYSHIRE HOSPITAL FOR SICK CHILDREN.—Female Resident Medical Officer for six months. Salary £200 per annum.
- DEVONPORT, ROYAL ALBERT HOSPITAL.—House Surgeon, unmarried. Salary £150 per annum, with board and laundry.
- DUDLEY, GUEST HOSPITAL.—Senior Resident Medical Officer. Also Assistant House Surgeon for six months. Salary £150 and £120 per annum respectively, with board, residence, attendance, washing.
- DUMFRIES, COUNTY OF DUMFRIES AND BURGHS.—Female Medical Assistants to Medical Officer of Health and School Medical Officer. Salary £250 per annum.
- ECCLIS AND PATRICKROFT HOSPITAL.—House Surgeon, unmarried. Salary £70 per annum, with board, residence, and laundry.
- EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Clinical Assistants in Out-patient Departments.
- GENERAL LYING-IN HOSPITAL, York-road, S.E.—Resident Medical Officer for three months. Salary £50 per annum, with board, &c.
- GLASGOW, CORPORATION OF THE CITY OF.—Vacancies among Junior Resident Medical Staff of City of Glasgow Fever Hospitals. Salary at rate of £160 per annum. Also Assistant Bacteriologist (two vacancies). Salary £250 per annum.
- GRIMSBY AND DISTRICT HOSPITAL.—House Surgeon.
- HALIFAX ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.
- HAMMERSMITH INFIRMARY AND WORKHOUSE, Ducane-road, Wormwood Scrubs, W.—First Assistant Medical Officer. Salary £220 per annum, with board, lodging, washing, and attendance.
- HAMPSHIRE COUNTY COUNCIL.—Bacteriologist. Salary 5 guineas a week.
- HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—Two Female Resident Casualty Officers for six months. Salary at rate of £50 per annum.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £30, with board, residence, &c.
- HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—Resident House Surgeon and Resident Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry. Also Resident House Surgeon. Salary £100 per annum, with board, laundry.
- KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing.
- LEEDS, GENERAL INFIRMARY.—Resident Medical Officer for six months at Ida and Robert Arthington Hospitals. Salary £60 per annum, with board, residence, and laundry.
- LIVERPOOL ROYAL INFIRMARY.—Two House Physicians, Three House Surgeons, and One House Surgeon to Gynaecological Department, all for six months. Salary at rate of £60 each per annum.
- LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Two House Surgeons and One House Physician, each for six months. Salary at rate of £60 per annum with board and residence.
- MAIDSTONE, KENT COUNTY ASYLUM.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, quarters, attendance, washing, &c.
- MANCHESTER, ANCOATS HOSPITAL, Mill-street.—House Physician. Salary £80 per annum, with board and residence.
- MANCHESTER CHILDREN'S HOSPITAL, Gartside-street.—Assistant Medical Officer for Out-patient Department for six months. Salary £100 per annum.
- MANCHESTER, COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.
- MANCHESTER, EAST LANCASHIRE TERRITORIAL FORCE.—Officers in East Lancashire (Second Line) Field Ambulance.
- MANCHESTER EDUCATION COMMITTEE.—Female Assistant School Medical Officer, unmarried. Salary £300 per annum.
- MIDDLBROUGH, NORTH ORMSBY HOSPITAL.—House Surgeon. Salary £150 per annum, with board, washing, and attendance.
- MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Senior House Surgeon for six months. Salary £100 per annum, with board, residence, and laundry.
- NEWPORT (MON.), ROYAL GWENT HOSPITAL.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.
- NORTH RIDING OF YORKSHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary at rate of £300 per annum.
- NORWICH, CITY OF.—Assistant School Medical Officer. Salary £30 per month.
- NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician for six months. Salary at rate of £100 per annum, with board, residence, and laundry.
- PAISLEY DISTRICT ASYLUM.—Assistant Resident Medical Officer. Salary £200 per annum, with board and apartments.
- QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician for six months. Salary £100 per annum, with board, residence, and washing.
- ROTHERHAM COUNTY BOROUGH.—Tuberculosis Officer and Assistant School Medical Officer. Salary £350 per annum, with board and residence at Kimberworth Tuberculosis Hospital, Rotherham.
- ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Male and Female House Physicians and House Surgeons for six months. Board, lodging, and washing provided. Also Acting Assistant Physician to have Care of Out-patients. Also Female Senior Obstetric Assistant. Salary £75 per annum, with board, lodging, and washing. Also Female Junior Obstetric Assistant. Board, lodging, and washing provided.
- ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at rate of £75 per annum, with board, lodging, and washing. Also Medical Officer for Prevention of Consumption Department. Salary £420 per annum.
- ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Third House Surgeon. Salary at rate of £50 per annum, with board and residence. Also Dental Surgeon.
- ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W.—Resident House Surgeon. Salary £100 per annum, all found.
- ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Junior Resident Medical Officer for three months. Salary at rate of £90 per annum, with board, residence, and laundry.
- SALFORD ROYAL HOSPITAL.—Junior House Surgeon and Casualty House Surgeon for six months. Salary at rate of £100 per annum each, with board and residence.
- SALISBURY GENERAL INFIRMARY.—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum respectively, with apartments, board, lodging, and washing.
- SCARBOROUGH HOSPITAL AND DISPENSARY.—Senior and Junior House Surgeons. Salary £100 and £80 per annum respectively, with board, residence, &c.
- SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon and Assistant House Physician.
- SHEFFIELD ROYAL INFIRMARY.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.
- SHEFFIELD UNIVERSITY.—Joseph Hunter Chair of Pathology.
- SHREWSBURY, ROYAL SALOP INFIRMARY.—House Physician. Salary at rate of £110 per annum, with board and apartments.
- SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £115 per annum, with residence, board, and washing.
- STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £180 per annum, with board, washing, and residence.
- TAUNTON AND SOMERSET HOSPITAL, Taunton.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and laundry.
- UNIVERSITY OF LONDON.—University Chair of Physiology at St. Bartholomew's Hospital Medical School. Salary £600 per annum.
- VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician and House Surgeon for six months. Salary £100 each, with board and lodging.
- WAKEFIELD, CLAYTON HOSPITAL.—Female Junior House Surgeon. Salary £120 per annum, all found.
- WARRINGTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.
- WEST HAM AND EASTERN GENERAL HOSPITAL, Stratford, E.—Junior House Surgeon. Salary at rate of £100 per annum, with board, residence, and washing.
- WOOLWICH INFIRMARY, Plumstead.—Resident Assistant Medical Officer, unmarried. Salary £180 per annum, with apartments, rations, and washing.
- WORCESTERSHIRE COUNTY COUNCIL EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £350 per annum. Also Assistant Tuberculosis Officer. Salary £350 per annum.
- YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £200 per annum, with board, lodging, and attendance.
- THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Northleach, in the county of Gloucester.

Births, Marriages, and Deaths.

BIRTHS.

McRAE.—On March 9th, the wife of G. Douglas McRae, M.D., F.R.C.P. Edin., Glengall House, Ayr, of a son.

DEATHS.

DOBIE.—On March 12th, at 4, Hunter-street, Chester, William Murray Dobie, M.D., aged 86 years.

KENT.—On Feb. 19th, at Tong Shan, North China, Anthony Lloyd (Tony), the second son of Dr. and Mrs. Hugh Kent, aged 1 year and 11 months.

KING.—On Dec. 13th, 1914, at his residence, 1315 Massachusetts-avenue, Washington, D.C., U.S.A., suddenly, of heart failure, Dr. Albert F. A. King, son of the late Dr. Edward and Louisa Freeman King, of Blackthorn, Oxfordshire, England, aged 73 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A MINIATURE COLONIAL MEDICAL SERVICE.

A REPORT on the Tongan or Friendly Islands Protectorate, prepared by Mr. H. E. W. Grant, C.M.G., the British Agent and Consul, has just been presented to Parliament. The islands in question, over which a British Protectorate was proclaimed on May 19th, 1900, are situated in the Southern Pacific to the E.S.E. of Fiji and 390 miles therefrom. They have an area of 385 square miles and a native population of about 23,000. The non-native population is estimated at 835, including 358 British, 133 German, and 45 American. The birth-rate per 1000 for the year 1913 was 35.89 and the death-rate 17.36. The following is an extract from a memorandum on the medical service of Tonga prepared by the chief medical officer, Dr. Arnold W. Izard: "At the three centres—Nukualofa, Haabai, and Vavau—hospitals have been established, each under a European doctor. Each hospital is a wooden building with two wards, male and female, a dispensary, operating theatre, and store-rooms. Native houses have been erected in each hospital compound for isolation cases. Each hospital has native medical students. Nukualofa has five, the other two four each. These boys do much of the work of the hospital, such as nursing, dressing surgical cases, and dispensing, under the personal direction of the local medical officer; they are paid by the Government of Tonga salaries varying from £2 a month for the junior boy to £5 a month for the head boy, according to the length of service and efficiency, being supplied with quarters, rations, and clothing. The policy of the department is to train the boys to fit them for appointment of dispensers in the outlying islands where there are no doctors. Already four such dispensaries have been opened at Mua, Nuafoou, Eua, and Nuaatobutabu. Small houses have been built for them of four rooms, including a dispensary, and they are supplied with dressings and drugs. They receive a salary of £6 a month and 30s. a month in lieu of rations. The dispenser at Mua is the head boy of the service, and he receives £100 a year without rations. The chief medical officer receives a salary of £500 a year, the medical officers at Haabai and Vavau £400 a year each. Each medical officer has the right of private practice, but all Tongan subjects, and all those who pay taxes, are treated at the public expense. A fourth medical officer has recently been appointed to Nukualofa, at a salary of £400 a year, to assist the chief medical officer in his duties and to allow him to visit the outlying islands. All the medical officers are supplied with furnished quarters. In addition to treating the natives they carry out the duties appertaining to the offices both of health officer and port health officer. As Tonga is within easy reach both of New Zealand and Australia, quarantine regulations are strictly carried out."

THE TREATMENT OF THE GASTRIC CRISES OF LOCOMOTOR ATAXY.

To the Editor of THE LANCET.

SIR,—Can any of my professional brethren help me? I am treating a case of locomotor ataxy in which the gastric crises are frequent, very severe, and extremely difficult to relieve. Salvarsan was followed by incessant vomiting and a dry brown tongue for nearly a week. Aspirin in 30 gr. doses every four hours gave no relief. Blistering epigastrium, the administration of alkalies and bismuth had not the slightest result. The only thing that has the least beneficial effect is morphia, which does not cause constipation with him, but is often attended with diarrhoea. I have pushed this to liq. morph. hydroch. 5i. every two hours by the mouth, with an occasional hypodermic injection of $\frac{1}{2}$ gr. of morphia when the pain is very severe, and am getting afraid to go any further, though even the hypodermic dose does not make him feel sleepy.

I enclose my card, and am, Sir, Yours faithfully,
March 8th, 1915. NEMO.

TURNING OFF THE GAS.

THE Portsmouth coroner recently investigated a case of poisoning by gas, in which the death of a young man was apparently due to a cause which may be of not infrequent occurrence. He and his newly married wife went to bed in lodgings which they had taken that afternoon at Southsea and were found insensible at 10 o'clock next morning, only the wife recovering. It appeared that the landlady, following her usual custom, had turned off the gas at the meter on going to bed, and on rising at 6 A.M. had turned it on again, while her lodgers were still asleep. It was conjectured that one of the new

lodgers, unaware of this practice, had tried to light the gas during the night, and having failed to do so owing to it having been turned off had left the burner open. Householders who, with the object of economy in view, turn off the gas at the meter at night and turn it on again early in the morning, should also remember that danger may well arise if the inmate of any room should happen to leave the gas alight after going to bed and should fall asleep. This might occur where all the members of a household knew that the head of it had the habit of turning off the gas at a given hour.

CENTIGRADE AND FAHRENHEIT.

To the Editor of THE LANCET.

SIR,—In his letter to THE LANCET of March 13th (p. 580) Dr. H. Alston criticises a statement in my letter of last week as to the range of body temperature in health. The appeal to the line on our charts and thermometers leaves me cold; but I admit that I have put the normal range somewhat lower than that which is given by various authorities. They differ as to the extent of the range, and mostly state one greater than either Dr. Alston or myself; but they agree with him in taking the upper limit to 99° F. or even (Wunderlich) to 99.5°.

Personally, I should have thought it was more common to find a temperature near 97° F. at the low time of the 24 hours (midnight, or 2 A.M.) than one of 99° at the higher. However, my object in writing was to suggest more than one *memoria technica* for the unfortunate Briton when trying to think in Centigrade figures. If the suggestion with regard to the range of normal temperature is unacceptable or misleading, I may leave it to the ingenious practitioner to work out one for himself.

March 13th, 1915.

I am, Sir, yours faithfully,
GRIMPEUR.

THE RED CROSS IN DENMARK.

THE movement for an improved system of sick-nursing, which at the time of the Crimean War began in England, Switzerland, and other countries, did not reach Denmark till much later, for Florence Nightingale's book on sick-nursing did not appear in Danish until 1861. The first effort made was to establish a "Deaconess" Institution which was inaugurated on May 26th, 1863, on the initiative of the Queen of Denmark, the Sisterhood at Kaiserswerth being taken as a model. The institution, which is situated in a suburb of Copenhagen, developed into a large institution and elevated nursing to a high standard all over the country. The Red Cross Society followed in the year 1875, 12 years after the conference at Geneva, but the condition of the country had long before taught the people to act up to the spirit of the Red Cross. During the three years' war in 1848-50 a committee was formed to organise private aid for the sick and wounded, which collected a large sum whereby many wounded and survivors had reason to be very grateful for the committee's assistance. When Denmark in 1864 had to fight alone against the allied powers of Prussia and Austria she considered it best to follow the national tradition and work on the foundation already laid. The committee of 1848 reassembled to renew its work with the same interest and energy as during the former war. One of the objects of the Red Cross Society was to prepare in time of peace well-trained nurses, and by the co-operation of the superintendent medical men of the larger hospitals it has been able to train a considerable number of nurses, whom it pays partly by yearly wages and partly in proportion to the nursing performed, and also puts by a certain sum towards a pension for them. The society also established Samaritan (Ambulance) Lectures in different towns on first-aid in industrial accidents, and caused placards to be posted at railway stations and seaports containing illustrated instructions for the resuscitation of the apparently drowned or suffocated and the treatment of the wounded until proper medical attendance can be obtained. In 1891 an excellent work, entitled "Denmark: its Medical Organisation, Hygiene, and Demography," was published in English at Copenhagen by a subvention of the Danish Government and presented to the Seventh International Congress of Hygiene and Demography held in London in that year.

A BYGONE BATH.

ONE of the old spas, so popular with Londoners in the eighteenth century, has just been exposed in the course of some building operations in connexion with a new substation for the Electric Parcel Railway in Phoenix-place, Clerkenwell, on the site of the old Cold Bath Fields Prison. In 1697 a spring on land then known as Garliners Farm was found to contain certain medicinal properties, and one Walter Baynes erected a bath-house over it for the treatment of patients suffering from general debility, nervous and scorbutic affections, and various chronic disorders. Those patients too weak to bathe were lowered

into the bath, which was very cold, in a dipping chair. It is a chalybeate spring, and deposits a saline incrustation, or did, if we may credit what we are told. Its supply was 20,000 gallons daily, the water rising in the marble basin to 4 ft. 7 in. The bath house stood in a walled-in garden and continued in use till 1811, when it was sold and the ground covered by some additions made to the prison. It is said that the old tread-wheel stood immediately over the site of the spring. The prison has been pulled down somewhat recently and certain Post Office buildings now occupy part of the site. This bath was not far from "The Bagnigge Wells," for Farringdon-road was originally the Bagnigge Wells-road.

Another interesting relic has also been revealed. The Old Fleet river ran across underneath the prison, and this also has come to light, giving a complete section showing the mottled clay foundation with the banks rising on either side covered with alluvium. The bottom is lined with gravel, probably rolled down from the Hampstead Heights, and over this is spread a thick bed of black mud in which have been found a few Roman sherds, gold pins, the bones of a horse, &c. Above this stratum was some 20 ft. of made ground on which this part of the prison was built in 1830. The main part was built in 1794. The whole of this land once formed part of the residential estate of the ill-fated Lord Cobham, better known as Sir John Oldcastle, who was burned alive for heresy at St. Giles's-in-the-Fields in 1417, and is believed to have been the original of Falstaff. The memory of this good man was retained until recently in Cobham-row, Clerkenwell, since demolished in the construction of Rosebery-avenue.

HEALTH OF BRITISH GUIANA.

THE Blue-Book of this colony for 1913-14, recently presented to Parliament, gives the estimated population as 304,149—157,972 males and 146,177 females. The birth-rate was 34.6 per 1000, as compared with a mean rate for the previous five years of 29.2. The birth-rate per 1000 of the population of each of the several races representing the community was: Europeans other than Portuguese, 10.6; Portuguese, 25.8; East Indians, 33.1; Chinese, 39.1; aborigines, 45.6; blacks, 32.3; and mixed races, 32.1. Of the births registered 59.6 per cent. were illegitimate. The death-rate for persons of white race was 13.1 per 1000 living. The general death-rate in 1913 was 24.2 per 1000 of the estimated population, this comparing most favourably with 29.2 in 1912 and 31.7 in 1911; the mean rate for the previous five years was 31.2. The deaths of children under 1 year of age was in the proportion of 179 per 1000 births, as compared with 190 per 1000 in 1912 and 229 per 1000 in 1911; the mean rate for the previous five years was 212 per 1000. The five principal causes of death throughout the colony were: malarial and other fevers, 17.9 per cent.; bronchitis and pneumonia, 13.1; bowel complaints, 12.7; kidney diseases, 7.8; and phthisis and other forms of tuberculosis, 6.7. Enteric fever is a notifiable disease; during 1913, 433 cases were notified, with 105 deaths. Anti-malaria and anti-mosquito measures are being generally and gradually enforced with visible signs of success. Ankylostomiasis, which has engaged the attention of the medical department for several years, has considerably decreased on the sugar estates, and this is attributed to improved sanitary measures and the erection of latrines. There are five public hospitals in the principal centres of population, and the outlying districts are served by dispensary hospitals and dispensaries. The immigration law also requires the maintenance of hospitals on every plantation on which there are indentured East Indian labourers, and these institutions are available for the treatment of emergency and pauper cases from the general community. There were 667 patients in the public hospitals at the beginning of the year, and 13,283 were admitted during the year, the daily average being 603. There were 1352 deaths. In addition to those admitted to hospital, out-door treatment was given to 46,345 persons. At the Leper Asylum there were 387 patients (266 males and 121 females) when the year began, and during the year 105 were admitted.

MORE LANGUAGE LESSONS FOR OUR TROOPS.

IN these days it is certainly of importance that our army, officers and men, should endeavour to pick up a nodding acquaintance with both French and German; there is no knowing when life may hang upon a prompt remark. The difficulty, of course, is to convey an idea of pronunciation of these languages by English phonetics. Several small pamphlets have already been published with this end in view. We have now before us "Easy German for our Men Abroad and How to Pronounce It," and a corresponding pamphlet on French, both by Captain Keyworth, which make a fairly good effort in that direction. But the vowel sounds are not interchangeable exactly, for the most part, and the movements of tongue

and lips dictate the exact sound produced. It is difficult to get the Englishman to put his lips in speaking. Since Indian troops are fighting side by side with English, "Easy Hindustani," by Colonel Alexander Masters, C.B., with Captain Keyworth, may also be useful. The pamphlets are published by Combridges, 56, Church-road, Hove, price 3d. each.

A CHILDREN'S GUEST HOUSE.

To the Editor of THE LANCET.

SIR,—Will you allow me the courtesy of space in your paper to put before your readers the following project? The Women's Freedom League is opening next month in Nine Elms (one of the poorest parts of London) a guest house for the children of the neighbourhood during the confinement of the mothers. We believe that two great objects will thus be served. First, the mother will get a chance of proper rest at a time when it is most necessary and her mind will be at ease as to the welfare of the other little ones of her family; and, in the second place, the children will be cared for while their mothers are laid up. We feel, with many others, that at this time of national crisis the future of England must not be handicapped by neglect of the future men and women. The time when our men are fighting and dying for our country is the very moment when those who stay at home should not only think for the future but also act.

The guest house will be worked by voluntary helpers and run in connexion with our penny dinner restaurant, which supplies on an average 250 dinners daily, and has more than justified its five months' existence. But money is needed for the rent of the guest house, its furnishing, and upkeep. I earnestly beg those who have the welfare of the women and children of the nation at heart to help us with funds, that not only in this district, but in many other parts of London and our great cities, these guest houses may be opened.

I am, Sir, yours faithfully,
C. DESPARD.

2, Currie-street, Nine Elms, S.W., March 15th, 1915.

AMBULANCE WORK IN INDIAN MINES.

THE Kolar Goldfield special centre of the St. John Ambulance Association has just made a donation of Rs.1278/1/- to the St. John Ambulance War Fund for providing comforts for the sick and wounded soldiers. This centre is one of the most active in India, and does an immense amount of useful work in the mines. It has its own ambulance competitions for trophies presented by the Mining Board, and is up to date in every particular.

COMPARATIVE POSOLOGICAL TABLES.

SOME useful "Posological Tables of the British Pharmacopœia, 1914" have been issued by Messrs. Jewsbury and Brown, of Ardwick Green, Manchester. The articles included in the Pharmacopœia, 1914, are listed in alphabetical order with the authorised dose in both metric and imperial measure, and the percentage strength. In parallel columns are given the dose (imperial measure only) and the percentage strength of the corresponding preparations in the Pharmacopœia, 1898. The book, which is a convenient size for the waistcoat pocket, is neatly covered in red canvas binding.

Cheval.—Either of the small cars would be satisfactory, but our leaning is towards the Singer. The Morris-Oxford is another good car on similar lines.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The following magazines, journals, &c., have been received:—Indian Journal of Medical Research, American Journal of Medical Sciences, Surgery, Gynecology and Obstetrics, Tropical Diseases Bulletin, Maryland Medical Journal, Journal of Nervous and Mental Diseases, Aberdeen University Review, American Journal of Roentgenology, Symons's Meteorological Magazine, British Journal of Dental Science, Canadian Journal of Medicine and Surgery.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Prof. B. Moore and Mr. W. G. Evans: On Forms of Growths resembling Living Organisms and their Products Slowly Deposited from Meta-stable Solutions of Inorganic Colloids.—Prof. B. Moore: The Production of Growths or Deposits in Meta-stable Inorganic Hydrosols.—Mr. H. Onslow: A Contribution to our Knowledge of the Chemistry of Coat-colour in Animals and of Dominant and Recessive Whiteness (communicated by Dr. F. G. Hopkins).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY.

The Council Club will dine at 7.30 P.M., at the Café Royal, Regent-street, W., and Members who desire to be present are requested to notify Mr. MacAlister not later than Monday, March 22nd.

THURSDAY.

SECTION OF NEUROLOGY (Hon. Secretaries—T. Grainger Stewart, H. Campbell Thomson): at 8.30 P.M.

Mr. J. Herbert Parsons: The Psychology of Traumatic Amblyopia following Explosion of Shells.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—Philip Turner, J. D. Rolleston, Sidney Gifford): at 4.30 P.M.

Cases:

Dr. E. G. L. Goffe: Four Cases of Ichthyosis in a Family of Six Children.
Dr. Edmund Cautley: Pulmonary Regurgitation.
Dr. Reginald Miller: Inherited Syphilis with Wassermann Reactions.
Dr. J. L. Bunch: (1) Ichthyosis associated with Long standing Superficial Ulceration of the Tongue; (2) Verrucae of Cheek.
Mr. Philip Turner: Diffuse Carcinoma of the Peritoneum in a Girl aged 14 Years.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY.—4.30 P.M., Lady Lugard: The Work of the War Refugees' Committee.

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—9 P.M., Annual Discussion on Recent Developments in Psycho-Therapeutics (introduced by Dr. T. B. Hyslop).
Dr. C. Miller, Dr. M. Wright, Dr. M. Bramwell, Dr. A. Buchanan, and others will take part in the discussion.

CHILD STUDY SOCIETY LONDON, Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY.—6 P.M., Mr. C. E. Wallis: The Care of the Teeth (illustrated by lantern slides showing School Dental Treatment in London). 7.30 P.M., Annual Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Lumsden Lecture:—Dr. S. Martin: Non-ulcerative Infections of the Colon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Arris and Gale Lecture:—Dr. F. Wood Jones: The Influence of the Arboreal Habit in the Evolution of the Reproductive System.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynaecological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

THURSDAY.—3 P.M., Dr. A. Strahan: The Ground Beneath London. (Lecture II.)

FRIDAY.—9 P.M., Prof. Sir J. J. Thomson, O.M.: Experiments in Low Cathode Rays.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Dr. C. E. Lea: Practical Demonstration of the Electrocardiograph.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

The Morison Lectures

ON

THE NEW PSYCHIATRY.

Delivered before the Royal College of Physicians of Edinburgh
on March 8th, 10th, and 12th, 1915,

By W. H. B. STODDART, M.D. LOND.,
F.R.C.P. LOND.,

LECTURER IN MENTAL DISEASE, ST. THOMAS'S HOSPITAL, ETC.

ABSTRACT OF LECTURE II.¹

(Delivered on March 10th.)

PSYCHO-ANALYSIS.

MR. PRESIDENT AND GENTLEMEN,—Psycho-analysis is a method of obtaining a complete history of the patient's illness and an insight into his modes of thought, such as can be obtained in no other way. A detailed history of a mental disorder includes an account, not only of the manifest disturbances of conduct, but also of the patient's thoughts in association therewith and of the various experiences and events which led up to it, together with their bearings on one another from the patient's point of view. When all this has been ascertained it becomes necessary to trace the patient's particular habits of thought back to their origin. Psycho-analysis achieves this result by reviving his memory for numerous incidents and events which he had forgotten, and by unearthing his hidden, repressed, and therefore unconscious, complexes. The relationship of these with the present disease is then discussed in such a way as to place these complexes in their true light, this being in reality a kind of re-education whereby the patient acquires self-realisation and develops his character and personality.

It is a duty for every physician who contemplates using the method either to be psycho-analysed or to psycho-analyse himself, so that he shall not read his own complexes into his patients. The process is not easy, even for those who have far greater experience of the method than I have, and it takes a very great deal of time. It is customary to spend with each patient an hour a day five times a week. It then takes a fortnight to obtain a complete history and a clear insight into the nature of the case and at least three months to accomplish a cure. Most cases take longer than this, and even Freud himself, purposely selecting very difficult cases, has spent as much as three years over a single patient before he effected recovery.

CASES SUITABLE FOR PSYCHO-ANALYTIC TREATMENT.

"What patients are suitable for psycho-analysis?" The patient must be intelligent. He must have some pretence to education, and I do not recommend the employment of this method with the labouring classes, although successful analyses have been reported. Similarly it is not wise, at any rate for a beginner, to attempt the analysis of young children, as it requires very special tact.

Also the patient must be willing to coöperate with you. You cannot analyse a patient who does not wish it. It is true that it is quite possible to learn much about his complexes by conversation and critical observation, but you will be unable to reveal them satisfactorily to himself. Then there is the type of patient who proclaims that he is perfectly willing to be analysed, but when the work has well begun he does not take

it seriously and plays his part in a desultory way. Such patients flit from one doctor to another, always dissatisfied with the last, and expect to be cured without making any effort themselves. All such patients should be left severely alone. Lastly, it is practically useless to attempt psycho-analysis on a patient who has passed middle age. At best, the analysis of a person who has passed his fiftieth year is sure to be lengthy.

In order to render clear what classes of mental disorder are suitable for analysis let me first explain how I classify them.

1. *The Neuroses*.—Neurasthenia, the anxiety neurosis, some forms of hypochondriasis.
2. *The Psychoneuroses*.—Hysteria, the compulsion neurosis, obsessions, morbid fears.
3. *The Psychoses*.—Maniacal depressive insanity, dementia præcox, paranoia.
4. *Confusional Insanities*.—Exhaustion insanities (from overwork, worry and mental shock), infection insanities (including febrile and post-febrile delirium), toxic insanities (from alcohol, haschish, belladonna).
5. *Thyroïgenous Insanities*.—Myxedema, exophthalmic goitre, cachexia strumipriva, cretinism.
6. *Epileptic Insanities*.
7. *Organic Insanities*.—From cerebral thrombosis, tumour, aneurysm or abscess, acute and chronic meningitis, general paralysis, Huntington's chorea.
8. *Chronic Cortical Atrophy*.—Insanities of involution (abiotrophic), arteriopathic dementia (syphilitic, senile, and renal).
9. *Congenital Mental Defect (Amentia)*.—Idiocy, imbecility, backward children, and so on.

[Here Dr. Stoddart gave his reasons for considering the last six groups unsuited for treatment, save certain forms of epilepsy and alcoholism, while the first three groups were all of interest to the medical psychologist. He proceeded, reversing the order:]

Maniacal-depressive insanity is a psychosis characterised by attacks of mania and melancholia, and it may be taken as a general rule that no attempt should be made to analyse these patients during the course of one of their attacks. A maniacal patient is in too excited a condition to coöperate, and psycho-analysis during an attack of melancholia tends to make the patient worse. The analysis should be undertaken between the attacks, and many medical psychologists have come to the conclusion that the analysis should not be pushed too far. A partial analysis of a few hours laying bare the most obvious of the patient's repressed complexes, which are very near the surface, is often sufficient to effect a permanent recovery; whereas anything like a complete Freudian analysis only does harm. Some of the most experienced psycho-analysts, however, disagree with me on this point. I ought to say that the psycho-analyst may often obtain a hint as to the nature of these complexes by a careful study of the patient's conduct, delusions, and apparently incoherent remarks during an attack; but the analysis itself should be postponed until the attack is over. Most of the cases of dementia præcox are too inaccessible mentally, while some of the earlier cases are too accessible, by which I mean that within a week of starting the analysis the patient has flooded you with an enormous tangle of repressed sexual complexes out of which there seems to be no possibility of escape. The most favourable cases are those of katatonia. I must warn the beginner against cases of dementia paranoides for his own sake. Negative transference, which I explain later, is liable to be set up and may induce the patient to inflict actual bodily injury upon his doctor, which may go as far as murder.

N

¹ Lecture I, was published in THE LANCET of March 20th, p. 583. No. 4778.

The same state of affairs may arise in the analysis of cases of paranoia, where we also encounter the difficulty that the patient suffers from a systematised delusional state on which he bases his whole attitude to the outside world, and refuses to believe that there is anything amiss with his mentation.

In Class 2 we come to the cases in which psycho-analytic treatment is pre-eminently satisfactory, though hysterical patients can be cured by other means. For psychasthenia, however, imperative ideas, obsessions, morbid fears, irrepressible thoughts and morbid impulses there is no other treatment than psycho-analysis, which is remarkably efficient and satisfactory. But, of course, no psycho-analyst claims that his method is infallible, even in cases of hysteria and psychasthenia.

The disorders of Class 1 are also suitable for psycho-analysis, but it is soon found that a complete psycho-analysis is unnecessary because the cause of the trouble is readily found and appropriate advice can be given accordingly. I shall refer to such matters in my next lecture.

TECHNIQUE.

[Dr. Stoddart next considered the technique, warning his hearers that the method made great demands on the doctor's time and sometimes on the patient's purse.]

The patient is first systematically examined and a provisional diagnosis made. All defects in physical health are remedied, such as errors of refraction, carious teeth, sources of septic infection, nasal obstructions, and so forth. When it has been decided that the patient is a suitable case for psycho-analysis he is directed to sit in a comfortable armchair by the consulting-room table more or less facing the doctor. This is my own method, but some physicians arrange that the patient shall face another way, so as not to be distracted by his examiner's changes of expression. Freud himself recommends that the patient lie on a comfortable couch and that the physician sit at the head of it so that the patient cannot see his face. Many physicians begin with an association experiment with the use of a galvanometer, sphygmograph, and stethograph, but in an ordinary patient all these instruments are mere accessories. A list of quite ordinary words, usually about a hundred, is read one by one to the patient. These are known as "stimulus words," and the patient is required to react to each in succession by stating the first word that comes to his mind in association with the stimulus word. The physician works with a stop-watch, and the patient is required to react as quickly as possible; a normal reaction takes about two seconds. Opposite each stimulus word the psycho-analyst writes the "reaction word" and the time taken by the reaction. I append here a list of suitable words, but it is as well for the doctor to introduce here and there words which appear to have some bearing upon the patient's own malady.

Quiet	Law	Correct	To play	Despise
Wall	Trouble	Pencil	Threaten	Tooth
Journey	Whisky	Woods	Habit	Book
Bible	Justice	Yellow	Dance	Wild
Apple	Work	Dream	Afraid	Box
Salt	Lion	Insolent	Child	Thirsty
Tobacco	Hammer	Ride	Sing	Hard
Cottage	Crowd	Soldier	Frog	Moon
Love	Paint	Thief	Proud	Glass
Sorrow	Rent	Green	Wool	Sympathy
Sheep	Ring	Joy	Doctor	Street
Water	To listen	Quarrel	Brother	Harm
False	Kiss	Choose	Men	To tell
Wash	Policeman	Deep	Health	Boy
Rich	Soft	Mouth	Mountain	Table
Dark	Stork	Anxiety	Rough	Duty
Window	Luck	Friend	Bed	Ink
Wish	Foot	Smooth	Girl	Carpet
Dog	Change	Dirty	Blood	Knee

These words are read through a second time and the associations again noted, but it is not necessary to record the reaction time on repetition.

The physician now searches his results for what are known as "complex-indicators." These are: (1) Undue prolongation of the reaction time—4 seconds or more; (2) failure to react to a word; (3) strange and incoherent associations; (4) apparent contradictions; (5) perturbation of several reactions following a certain association; (6) failure to react with the same word on repetition of the test; (7) accompanying motor and vaso-motor phenomena, such as restlessness, lip-biting, nail-picking, blushing, &c.; (8) increase of frequency of the pulse and respiration; and (9) the generation of weak electrical currents by the body, or, if a cell is introduced into the circuit, alteration of the electrical resistance of the body. By a little detective work it is often possible to make a shrewd guess at some of the patient's repressed complexes; but your own conclusions should never be communicated to the patient. It is legitimate to ask him a question which forces him to admit something that he is obviously withholding, but it is not permissible to do more than this.

The various "complex-indicators" just mentioned are due to intrapsychic "resistances." Some of these are between the preconscious and the conscious, and constitute resistance to a disclosure of the complex to you. Others are between the unconscious and the preconscious, and constitute a resistance to disclosing an unconscious complex to the patient's own consciousness, and incidentally to you. These "resistances" have to be overcome, and the method is to take each of the associations which have revealed themselves as complex-indicators and get the patient to explain them. This he can very readily do with many of his associations by relating some incident in his past experience. Some will prove valueless and be discarded, others worth noting. Some of his associations, however, will turn out to be a puzzle to himself. These are important and should be followed up. What is called "continuous association" may first be tried, the patient being told not to stop at the first association, but go on from one word to another until some light is thrown on the first association; or the particular reaction may be used as a starting point for a "free association" to be described presently. If during a series of continuous associations the patient comes to a stop, a block, a resistance, he should be urged to find an association. You say to him, for example, "Go on, you must think of something!" Then, after a short pause, especially when he shows some motor restlessness, "What is in your mind now? You must tell me." In this way you work through all the reactions and by the end of the test you have a very fair amount of material to work upon.

Free Association: Overcoming Resistances.

The method of "free association" is conducted in much the same way, except that no stimulus words are given. The patient is directed to make himself quite comfortable and to assume a passive, inert frame of mind. He is then told to allow his thoughts to flow as they will, and to exercise no control of them whatever. As they flow in this way he is to speak everything that comes to his mind; no matter how incoherent his speech may seem and no matter how painful or repugnant the thought may be, he must speak it out. He is to allow his thought and speech to run wild. In this way his associations will here and there tap the unconscious. After a few sittings you can sometimes tap the

unconscious almost as soon as he enters the consulting room by making some utterance which calls for no special reply, such as "Yes?" or "Well?" and waiting for him to speak. It may seem ungracious or unceremonious that you should not enter into the conversation, but you must let him do all the talking.

In the course of a free association you will again come across "resistances." The patient will tell you that his mind is a blank and that he can think of nothing. You reply, "Never mind! go on talking." Or he will become silent. Your reply is to become silent too. You wait for seven or eight minutes sometimes, looking at him expectantly the whole time until something comes up from the unconscious; or you interrupt the silence suddenly with "Talk! what is the matter with you? Go on talking!" or, at the slightest sign of restlessness, you say, "What are you thinking of now? Why don't you tell me?" These resistances are difficult to describe because they vary so much with different patients. I have seen a patient fall over the side of the chair, as if collapsed, remarking "Oh doctor! what are you doing to me?" a patient, mind you, who went about his business during the rest of the day as if there were nothing the matter with him, although he was constantly tormented by psychomotor hallucinations and other symptoms.

From time to time it is well to recapitulate to the patient what he has told you and get him to draw his own conclusions as to the nature and cause of his malady. I wish to insist a little on this point, that he tells you and that you do not tell him, because the critics like to say that the psychoanalyst puts suggestions into the patient's mind. It is true that the patient will sometimes ask, "Is that right, doctor?" to which my usual reply is, "Of course it is right, because it is your mind that has come to this conclusion, not mine, and the malady is yours, not mine." Sometimes, of course, it is necessary to counteract some absurd conclusion, but I have found that such conclusions usually originate in a suggestion given to the patient by another person. Beginners in psycho-analysis are liable to make this very mistake. They tell the patient their conclusions as to the nature of his complexes before he has discovered them for himself. These are what Freud has termed the "wild psychoanalysts." Sometimes their conclusions are correct, sometimes incorrect. One patient of mine told me that a certain doctor after one week's analysis informed him that he was in love with his mother, to which, not understanding what was meant, he replied, "Of course I'm in love with my mother." Now it happens that the doctor was right; the patient's libido was unconsciously fixated on his mother, so much so that although the patient was 40 years of age and had been in love many times, he could never bring himself to marry the girl of his choice. Psycho-analysis, as a method of bringing hidden complexes to light, has been compared to opening an abscess; but this doctor's method was more like hitting an abscess, not opening it.

I can here foresee an objection that there is no need for the psychologist if he is not allowed to supply interpretations of the patient's data or even to engage in conversation, and I have indeed had the experience of a patient who, while admitting her recovery, remarked, "But I do not see what you have done." I accepted that as a very great compliment.

As a matter of fact, the work of the psychologist is at times very great at overcoming resistances,

which sometimes last for several sittings. One form of resistance for which you must be on the watch is what the Germans call "vorbeireden"—as we should say, "talking past the point." The patient suddenly becomes loquacious and hurries past a certain association, just as a hostess at a dinner-party may suddenly become talkative and change the conversation, knowing that it is getting dangerously near a tender subject for one of her guests. The analyst's duty is the reverse of this. He brings his patient back to the point, discusses it right out, and perhaps starts a new series of associations. Then again it is desirable to encourage associations which promise to revive infantile memories. Such memories are usually strongly visual and difficult to associate with words; it is therefore well on such occasions to ask the patient to close his eyes, to see pictures and to relate what he sees. Indeed, it is helpful in all psycho-analysis that the patient should keep his eyes closed. His mental and bodily attitude should resemble that of going to sleep, in that the mind should be allowed to wander, but there is the difference that the subject's attention is directed to his own psychical activities. Of course, he requires a certain amount of practice before he is able to do this successfully. His part of the work is by no means easy, and many a patient attains peace of mind at the expense of his hair turning grey; not as a result of the difficulty of technique, but as a result of overcoming resistances.

SIGNIFICANCE OF VARIOUS INCIDENTS AND HABITS.

[Dr. Stoddart here considered the interpretation of dreams, which Freud has designated the "royal road" to the unconscious, and which he considered very helpful in psycho-analysis, adding that many suggestions from apparently trifling incidents and habits occurring in the patient's everyday life will also be found valuable. He proceeded:]

A common experience of psychoanalysts is that patients leave some of their belongings after a satisfactory interview. This is an unconscious way of expressing a wish to return for further treatment. People who have displayed a tendency during childhood to pilfer or lie and who still have an unconscious tendency in the same direction, are scrupulously careful to pay for everything "on the nail," as the saying is, or to be excessively precise and truthful whenever they make a statement. A spendthrift usually has all the apparatus for saving money—cash-box, ledger, day-book, and the rest of it—but his unconscious tendency prevents him from using them. These are generalities, but patients and others often supply particular examples of the work of the unconscious. Dr. Bernard Hart quotes a patient, for example, who had an irresistible impulse to examine the number of every bank note which came into her hands. Analysis revealed that this habit dated from an association when she asked a man with whom she was in love to change a coin for her. He complied with her wish, and putting the coin in his pocket said that he would not part with it. This remark raised her hopes that her love was reciprocated and any money passing through her hands always reminded her of the incident. The man passed out of her life, however, and she strove to banish the episode from her memory and to forget that such a desire ever crossed her mind. The repression was successful and the complex was thenceforward only allowed to enter consciousness in disguise—viz., as an interest in money—which became crystallised into her exaggerated pre-occupation with the numbers of bank notes.

Freud has demonstrated that the forgetting of proper names, far from being fortuitous, is always due to the activity of the intrapsychic censor. Whenever a name is forgotten or incorrectly remembered a reason can always be discovered, usually by a quite superficial analysis, why it has been forgotten. Some disagreeable memory is the common cause, associated either with the individual or with a person or place of the same or a similar sounding name. In other words, the forgetting is neither more nor less than a repression. Examples of this occur in everybody's experience every day. I always have a difficulty in remembering the name of a certain town in Italy, Ferrara, where—owing to a piece of foolishness—I had to run for nearly a mile in record time (for me) in order to catch a train in which I had already placed my luggage. The forgetting of resolutions belongs to the same category of unconscious phenomena, the commonest example being that we are more liable to forget having borrowed money than having lent it, although none of us would admit to ourselves that we have dishonest propensities.

The mislaying of objects gives another series of clues to the unconscious. Bills are more apt to be mislaid than cheques. If a cheque is mislaid, you will find that you have a feeling that you have not given sufficient value for the money or that you have failed to declare it to the income-tax authorities, or that you do not like the person who gave it to you, or there is some other unpleasant association with the cheque. Mistakes in speaking, reading, and writing (*lapsus linguae et calami*) belong to the same category. They are betrayals of repressed complexes, and no psychoanalyst allows such a mistake made by himself to pass without searching for the hidden cause of it. Similarly, he always gets his patients to relate to him such symbolic actions, failures of memory, and lapses of the tongue and pen, so that he may investigate them and thus gain access to the unconscious tendencies of his patients.

Perhaps I ought to mention two other methods of tapping the unconscious, which do not, however, belong to psycho-analysis proper—viz., Hypnosis and Crystal-gazing. I prefer if a person is to be psycho-analysed that he should not be hypnotised. Crystal-gazing does not require much practice and is quite easy for a neurotic patient. He is directed to abstract his mind from all normal sensory impressions and to gaze intently into a glass sphere. A black background is preferable, and it is advisable not to have too much illumination. Clouds appear in the ball at first, which advance and retire synchronously with respiration. Then many reflections are unconsciously combined to form an illusory picture, which is at first vague and indistinct. Definite hallucinations then form which ultimately take on movement. These hallucinations represent some forgotten incident of the past life of the individual, with much less distortion than takes place in dreams. The percipient, being detached from surrounding impressions and awake to those of his own sub-conscious self, is probably in a mild state of hypnosis. The patient relates to the physician all that he sees in the crystal ball, and, the memory of some incident having been revived, he is urged to connect it with his present content of consciousness by the association methods already described. The method is not much used, but I have sometimes found it helpful in overcoming resistances in the interpretation of dreams.

THE TRANSFERENCE.

In the first lecture I explained that every constellation of ideas which we call a "complex" is possessed of a certain amount of psychical energy or libido, desire *plus* a conative trend; and it is this libido which usually conflicts with the herd instinct and brings about that mental conflict which secures adjustment by repression of the whole complex into the unconscious. Fixation of the libido in the unconscious may be on the father (Edipus-complex), on the mother (Electra-complex), on a person of the same sex as the patient (homosexual-complex), on a person of the opposite sex who has passed out of the patient's life, or even on an inanimate object (money, for example). When, therefore, by the methods I have described an unconscious complex becomes conscious, this libido becomes conscious too, but this time its object is not available. The method of psycho-analysis has itself divorced the libido from its former object. There is therefore a certain amount of libido, synonymously psychical energy, floating free, so to speak. What becomes of it? Such a state of affairs cannot possibly persist. It becomes attached to, or fixated on, the personality of the physician. This is a stage which must be attained by every patient and is known as "the transference." To some extent a similar feeling of dependence and confidence occurs in every patient, whether he be suffering from heart disease, phthisis, cancer, or any other organic disease; but it is enormously exaggerated in the neuropath who is undergoing treatment.

All Psycho-analysis Proceeds *via* Transference.

Psycho-analysis means using transference for the purposes of treatment, it being the only way in which buried memories can be recovered. It is often difficult to see how on earth certain infantile fixated relationships can possibly be transferred to the physician, but the patient's unconscious mind discovers a way, usually with the help of a dream. When, as commonly happens, the infantile fixation is of a hostile nature the patient's unconscious mind is most insulting to the physician, although superficially he is as polite as ever. Under such conditions, when the transference has been effected, it may be very disagreeable, and indeed dangerous. In patients suffering from delusions of persecution, for example, the patient then regards the physician as his persecutor. Jung of Zürich told me of a patient of his who presented him on recovery with a loaded pistol which, during the stage of transference, was intended to be levelled at him. This is known as "negative transference." It must never be forgotten that during the transference the neurosis is as active as ever. There is a recrudescence of many of the symptoms of the former neurosis with the difference that some earlier person is replaced by the person of the physician. A similar transference on the part of the physician has to be guarded against ("reversed transference" it is called) and is to be avoided by self-analysis.

It is the commonest complaint of neurotic patients that they are not understood, but in the psychoanalyst they have found a man who listens sympathetically, tries to understand them and never gets annoyed by their constantly recurring resistances. The doctor has become a kind of father confessor who has penetrated the secrets of his soul far deeper than any father confessor ever does, while the patient has found a prop against which he may lean for evermore. He considers the

situation ideal, and resists all attempts to alter it, even reverting to all his former phantasies in their new relationship. This is the state in which the father confessor would leave him, but the psycho-analyst must place the patient upon his own feet. In other words, the next stage in the treatment is dissolution of the transference relation. This is the most difficult part of psycho-analysis, because the resistances are as strong as ever. It is to be accomplished in exactly the same way in which the transference relation was produced—viz., by psycho-analysis. In this dream interpretation will again play an important part, for it will now prove a useful guide in our search for the future object of the libido. We must find new interests for the patient and encourage him in them, so that he may come once more into practical relationship with the world around him. During this process all his symptoms crumble away, and in the end he finds himself neither better nor worse than other members of the community around him, but just a normal person.

TYPHOID AND PARATYPHOID INFECTION.*

No. II.—THE DETECTION AND IDENTIFICATION OF B. TYPHOSUS AND B. PARATYPHOSUS.†

By GEORGES DREYER, M.A. OXON., M.D. COPENHAGEN,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF OXFORD;
HONORARY CONSULTING PATHOLOGIST TO THE THIRD
SOUTHERN GENERAL HOSPITAL;

E. W. AINLEY WALKER, M.A., D.M. OXON.,
LECTURER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD;
HONORARY ASSISTANT CONSULTING PATHOLOGIST TO THE
THIRD SOUTHERN GENERAL HOSPITAL;
AND

ALEX. G. GIBSON, D.M. OXON., F.R.C.P. LOND.,
LECTURER IN MORBID ANATOMY IN THE UNIVERSITY OF OXFORD;
CAPTAIN, R.A.M.C. (T.); PATHOLOGIST TO THE THIRD
SOUTHERN GENERAL HOSPITAL.

THE problem of the detection of the B. typhosus and the paratyphoid bacilli resolves itself into a question of the application of methods which will reveal the presence of these organisms in mixed cultures of a variety of bacteria even when their relative numbers are very few; as, for example, in the faeces of convalescents or carriers. Where typhoid (or paratyphoid) bacilli are abundant almost any method, from plating high dilutions over large surfaces of ordinary agar to the use of the most elaborate media for the enhancement of the B. typhosus on the one hand, or the inhibition or elimination of its rivals on the other, will render the isolation of these organisms a comparatively simple process. But where they are few negative results are frequently obtained even after repeated examinations of the faeces.

In bringing forward the results described below it is not our object to enter into any detailed criticism of existing methods, many of which have been shown to possess very considerable value for particular purposes. A discussion of their respective merits and demerits does not lie within the scope of our present purpose, which is to point out briefly why negative results obtained by their use are often likely to be entirely misleading where relatively few of the bacilli are present. At the same time we wish to describe a new method of which the essential feature is an exposure of the suspected bacterial material to the influence of

actinic light. This method allows of the examination of much larger quantities than usual of the material in question with very little labour, and has enabled us to detect the B. typhosus or B. paratyphosus at the first examination where examination by other methods had again and again yielded negative results. For example, from a suspected carrier examined elsewhere on five different occasions with negative results, we isolated a few colonies of the B. typhosus at the first examination by the new method, though other methods tried at the same time gave a negative result.

Inhibitory Media.

In examining suspected carriers and in studying the persistence of typhoid and paratyphoid bacilli in the urine and faeces of convalescents from typhoid and paratyphoid fever, we have met with constant disappointment in the results obtained by using the various special media which have been recommended for the purpose. With most of these media the amount of the suspected material which can be worked up for investigation is relatively very small unless the number of platings made is largely increased. Any considerable multiplication of platings is, however, impossible when many examinations have to be carried out within a short period. Thus if only relatively few of the bacilli are present in the material examined they are likely to be missed.

But besides this difficulty, the rate at which typhoid and paratyphoid bacilli frequently appear to vanish during convalescence from faeces which are investigated by these methods forced upon us a suspicion of the possibility that the eliminating substances employed were actually destroying the bacilli sought for as well as those which it was intended to inhibit.

In view of the importance at the present time of retaining convalescent soldiers under observation and control until they cease to act as carriers it is essential that the method used in making examinations should be one in which a negative finding represents as nearly as possible a true negative. And an ideal method would be one where the report "not found" could be accepted as a true equivalent of "not present." But this can never be the case if the media employed are such as may destroy or inhibit the bacilli which are being sought for.

That the method of direct plating on so-called selective media often proves misleading has been shown by various observers, and notably C. H. Browning¹ and his co-workers who found in the course of their important work with brilliant green that direct plating on MacConkey's medium was unsatisfactory. It only enabled them to detect typhoid (or paratyphoid) bacilli in 6 cases out of 13, in all of which they were discovered by their method of "enhancement." Even in this latter method, however, as well as in its later modification by the addition of potassium tellurate² to the fluid used for the primary cultures plating on a special medium follows the enhancement. Accordingly we found it necessary to submit a series of the recognised selective media to actual tests as regards their effect upon the growth of different members of the colityphoid group.

Among the numerous special media which have been proposed the best known are those

* The expenses of this work have been defrayed out of a grant received from the National Medical Research Committee.

of Drigalski and Conradi,³ MacConkey,⁴ Endo,⁵ Lentz and Tietz,⁶ Löffler,⁷ Conradi,⁸ and Fawcus.⁹ Of these media those of Drigalski and Conradi, MacConkey, and Endo were ultimately selected for special quantitative investigation. A very extensive series of experiments has been carried out; but it will be sufficient for our purpose to quote a few typical examples of the results obtained on these media with pure cultures, and with mixtures of pure cultures of *B. typhosus* and *B. coli* in different proportions. The paratyphoid bacilli have also been investigated in a similar manner. Experiments were made by preparing (a) high dilutions of pure cultures of *B. typhosus* and *B. coli* and (b) known mixtures of these pure cultures, and comparing the number of colonies of the two organisms which grew after plating on the surface of agar plates with the number of colonies obtained from the same quantity of the same dilution on the surface of plates of the three special media named.

We have not found in the literature that exact quantitative tests of the viability of typhoid, paratyphoid, and colon bacilli on such media have previously been made. Our results seemed so surprisingly contrary to expectation that the experiments were many times repeated for complete confirmation. The outstanding conclusion is that all these media eliminate a very large proportion of typhoid (and even paratyphoid) bacilli, and do not to any very notable degree inhibit the growth of *B. coli*. In saying this we do not at the present time at all intend to suggest that such media as those of Endo, MacConkey, and others are not excellent for the differentiation of these micro-organisms and for separating them when sufficiently abundant from a variety of intestinal and other organisms by selective elimination. But we maintain that for the isolation of typhoid and paratyphoid bacilli where they are relatively few in numbers, as in drinking water, in carriers, and in convalescent cases, their use is entirely misleading as regards the value of a negative finding.

Before giving figures for some typical quantitative experiments it is of interest to draw attention briefly to the results obtained by inoculating from pure cultures of typhoid, paratyphoid, and colon bacilli on plates of MacConkey's and Endo's media and ordinary agar. In each case the needle was charged from a single isolated colony and a streak was made on the surface of each medium in succession, beginning with MacConkey's medium and ending with the ordinary agar without recharging the needle. One example for each organism is given in Table I.

In other cases a series of mixtures of pure cultures of *B. typhosus* and *B. coli* in different proportions was prepared (e.g., 1 to 1, 1 to 5, 1 to 10, 1 to 15, &c.), and from these streaks were made on a series of media by means of a platinum needle recharged for each medium. The *B. typhosus* was not found on Drigalski and Conradi's medium or on MacConkey's medium when present in a mixture in a less proportion than 1 typhoid to 10 colon bacilli.

In the case of Endo's medium (and the medium of Lentz and Tietz) the *B. typhosus* was recovered from mixtures of 1 typhoid to 15 colon bacilli, but not from any lower proportion of typhoid to colon bacilli.

TABLE I.

Medium.	Experiments		
	(a) <i>B. typhosus</i> .	(b) <i>B. paratyphosus</i> (B).	(c) <i>B. coli</i> .
MacConkey's medium...	Slight growth.	Fair growth.	Rich growth.
Endo's medium	Slight growth.	Marked growth.	Very rich growth.
Ordinary agar '... ..	Luxuriant growth.	Luxuriant growth.	Luxuriant growth.

Quantitative Experiments.

The dilutions were carried out with accurately graduated pipettes, and were made with sterile bouillon of the same batch as that in which the cultures were grown. The platings were always made with 20 c.mm. of the diluted culture (or mixture) measured by means of calibrated capillary pipettes. The fluid was placed on the surface of the medium and carefully spread over the whole area by continued gentle rubbing to and fro with a thinly drawn Pasteur pipette the last inch of which was bent at a right angle after sealing and turning up the end. The plates employed were Petri dishes of 9 cm. diameter and always contained the same amount of medium. The various media used in each set of experiments were prepared at the same time, and plates for each set were poured at the same time and were brought into use together after standing at the room temperature for a period of 8 to 24 hours.

TABLE II.—Showing the Number of Colonies which Grew on the Various Media in Experiments made with Various Known Dilutions of Pure Cultures of *B. Typhosus* and *B. Coli* respectively. (The experiments denoted by the same number were made at the same time in each case.)

Medium.	Number of colonies on plates inoculated with <i>B. typhosus</i> 20 c.mm.			Number of colonies on plates inoculated with <i>B. coli</i> 20 c.mm.		
	Experiments			Experiments		
	(1)	(2)	(3)	(1)	(2)	(3)
Ordinary agar	265	150	90	1100	550	86
Endo's medium	245	135	85	1000	500	60
MacConkey's medium	2	1	0	950	450	70
Drigalski-Conradi medium...	2	0	0	1050	500	64

The above table shows clearly that when relatively small numbers of typhoid bacilli are plated out they may entirely fail to grow on MacConkey's and the Drigalski-Conradi medium, even when there are from one to two hundred bacilli viable on ordinary agar present. Endo's medium, on the other hand, grew the great majority of the viable typhoid bacilli. This, however, is not the case unless the plates of Endo's medium are only very moderately dried before use. If Endo-plates and ordinary agar plates are allowed to stand for two or three days before use the Endo's medium becomes relatively very much more unfavourable. Thus in one case with 457 colonies on agar there were only 140 colonies on Endo's medium, and in another case with 100 colonies on agar only 4 of the bacilli grew on Endo's medium. As regards the *B. coli*, it will be observed that of the organisms viable on ordinary agar the great majority grew on all the media, though in this respect our general experience has been that MacConkey's medium is usually the least favourable of the three.

⁹ Fawcus: Journal of the R.A.M.C., vol. xii., p. 147.

TABLE III.—Showing the Number of Colonies of *B. Typhosus* and *B. Coli* respectively which Grew from Mixtures made at the Same Time from the Same Cultures so as to contain (A) 3 *B. Coli* to each *B. Typhosus* and (B) 149 *B. Coli* to each *B. Typhosus*. (The mixtures were diluted 1/62500 before plating.)

Medium.	A 3 <i>B. coli</i> to each <i>B. typhosus</i> . 20 c.mm.		B 149 <i>B. coli</i> to each <i>B. typhosus</i> . 20 c.mm.	
	Typhoid colonies.	Coli colonies.	Typhoid colonies.	Coli colonies.
Ordinary agar... ..	133	430	1	500
Endo's medium	120	400	0	450
MacConkey's medium... ..	1	460	0	420
Drigalski-Conradi medium	0	303	0	400

Here it appears that even when there is one *B. typhosus* to every three *B. coli*, and there are upon the plates almost the extreme number of colonies which will usually allow of certain differentiation, only a single typhoid colony appeared on MacConkey's medium and none on the Drigalski-Conradi medium.

Experiment B shows how, as the dilution of the *B. typhosus* with *B. coli* increases, the number of *B. typhosus* found even on an ordinary agar plate diminishes below the expectation, only one colony being found instead of three. This we have found to be our regular experience.

TABLE IV.—Showing the Number of Colonies of *B. Typhosus* and *B. Coli* respectively which Grew from Mixtures made at the Same Time from the Same Cultures so as to contain (C) 1 *B. Coli* to each *B. Typhosus*, and (D) 19 *B. Coli* to each *B. Typhosus*. (The mixtures were diluted 1/62500 before plating.)

Medium.	C 1 <i>B. coli</i> to each <i>B. typhosus</i> . 20 c.mm.		D 19 <i>B. coli</i> to each <i>B. typhosus</i> . 20 c.mm.	
	Typhoid colonies.	Coli colonies.	Typhoid colonies.	Coli colonies.
Ordinary agar	100	132	4	150
Endo's medium	75	114	3	136
MacConkey's medium ...	1	121	0	161
Drigalski-Conradi medium	2	75	0	152

Here it is seen that only when the number of *B. typhosus* present approximately equals the number of *B. coli* are any colonies of *B. typhosus* found on MacConkey's or the Drigalski-Conradi medium. Observations such as those recorded in Tables II., III., and IV. are typical examples of the results obtained in numerous experiments with different media recommended for the isolation of the *B. typhosus*. They are sufficient to explain the fact (emphasised most recently by Browning, Gilmour, and Mackie in the case of MacConkey's medium) that primary platings on selective media frequently fail to yield colonies of *B. typhosus*, even when that organism is undoubtedly present. If a selective medium is employed at all at any stage of the isolation and identification of *B. typhosus*, the medium of Endo is to be recommended. The results with that medium in the tables shown are good. But this will only be the case, as already stated, if the medium is very carefully managed as regards its relative moisture.

For purposes of cultural discrimination between *B. coli* and *B. typhosus* Endo's medium constitutes the most beautiful differential medium with which we are acquainted. The colonies of *B. coli* are

well developed, of a deep red colour, and gradually acquire an intense metallic sheen, while those of *B. typhosus* are at first only faintly rosy in colour, and though they eventually become red they never acquire any metallic lustre.

TABLE V. (Mixture A).

Enhancement.	Medium.	Streak.	Colon.	Typhoid.
a.	Ag.	1	Continuous growth.	1 isolated colony found.
		2	Numerous isolated colonies.	No colonies.
		3	Isolated colonies.	2 isolated colonies.
	E.	1	Continuous growth.	No colonies found.
		2	Fairly continuous growth.	3 isolated colonies.
		3	12 colonies.	8 colonies.
β	M'C.	1	Continuous growth.	No colonies found.
		2	Continuous growth at first, then isolated colonies.	No colonies found.
		3	Isolated colonies.	No colonies.
	Ag.	1	Numerous isolated colonies.	More numerous isolated colonies.
		2	No colonies.	No colonies.
		3	No colonies.	1 colony.
γ	E.	1	Continuous growth at first, then isolated colonies.	18 isolated colonies towards end.
		2	1 colony.	1 colony.
		3	No colonies.	No colonies.
	M'C.	1	Numerous isolated colonies.	2 colonies.
		2	3 colonies.	No colonies.
		3	2 colonies.	No colonies.
γ	Ag.	1	13 colonies.	4 colonies.
		2	No colonies.	No colonies.
		3	No colonies.	No colonies.
	E.	1	2 colonies.	18 colonies.
		2	No colonies.	No colonies.

The Method of Enhancement.

It is no part of our present intention to discuss in detail the brilliant-green enhancement method of Browning, Gilmour, and Mackie. In their hands, and in those of other observers, it has yielded very satisfactory results. Besides its action in the enhancement of the *B. typhosus*, the use of brilliant green has the advantage of exerting a bactericidal action on Gram-positive organisms. This action of the group of dyes to which brilliant green belongs was first demonstrated by two of us in work carried out with Kriegler^{10,11} and with S. G. Scott.¹² It has been fully confirmed by Browning and his co-workers, as well as by Krumwiede and Pratt¹³ and others. Browning, Gilmour, and Mackie further showed that brilliant green, which contains four ethyl groups in place of the four methyl groups of malachite green, is more favourable to the enhancement of the *B. typhosus* than the latter, which had been used by Löffler, Lentz and Tietz, and others.

As regards the practical utility of the brilliant-green enhancement method (which would be employed in preference to the later method with potassium tellurate¹⁴ added where there was possibility of the presence of *B. paratyphosus* (B)) we venture to suggest a modification. Browning plates out the enhanced cultures on MacConkey's medium. If they are plated out on Endo's medium or on ordinary agar instead, the chance of finding *B. typhosus* or paratyphoid bacilli, if present, is very greatly increased, as the following observations show.

Of the undiluted mixtures A and B in Table III. 20 c.mm. were added to two series of brilliant-green peptone-water tubes according to the method of Browning, Gilmour, and Mackie. Each tube contained precisely 5 c.c. of the medium. After 24 hours' growth at 37° C. the cultures were plated on ordinary agar, Endo's medium, and MacConkey's medium by making three successive strokes on each medium with a narrow loop. The loop was recharged for each plate. The results from three different strengths of brilliant green (1/10,000 solution 0.15, 0.4, and 0.8 c.c., indicated by α , β , and γ respectively) are shown in Tables V. and VI.

What Table V. shows is that, in accordance with the quantitative estimates given in previous tables, MacConkey's medium is inferior to Endo's medium and to ordinary agar for the detection of the *B. typhosus* after enhancement. Its use may lead to negative findings even when typhoid bacilli are actually present in some numbers.

Table VI. again shows the disadvantage of plating on MacConkey's medium after the enhancement. In all three cases the *B. typhosus* failed to appear on plates of this medium, although it was found both on Endo's medium and on ordinary agar. It may be added that on diluting the brilliant-green peptone-water culture β of Table VI. to 1/250 and plating out 20 c.mm. of the dilution by spreading on the surface of poured plates of ordinary agar, Endo's medium, and MacConkey's medium, about 100 colonies of *B. coli* were found on each medium, with two colonies of *B. typhosus* on the agar, one colony on Endo's medium, and none upon MacConkey's medium. Thus, as the result of the enhancement the relative number of *B. coli* had

decreased and the number of *B. typhosus* had increased both relatively and absolutely. The ratio found on plates before enhancement was 1 *B. typhosus* to about 500 *B. coli* (see Table III., B), but had now become 1 or 2 *B. typhosus* to each 100 *B. coli*.

The Light Method.

Although the method of enhancement has yielded excellent results, it has the drawbacks that a considerable number of enhancing cultures are required to make sure of including the most favourable concentration of brilliant green, and that it lengthens the process of isolation by some 24 hours. In the method which we are now about to describe relatively large quantities of the suspected material are

FIG. 1.

The lamp employed by the authors for exposure of the agar plate to the arc light.

worked up for examination and isolated colonies of *B. typhosus* or *B. paratyphosus* (A) or (B) may be obtained within 12 to 24 hours by the use of a single plate. The method was devised by one of us (G. D.) and is based on the experience of numerous previous investigations on the biochemical action of actinic light. It consists in the subjection of an ordinary agar plate liberally spread with the bacterial emulsion to a graduated exposure to the rays of an arc light. The arc formed between silver electrodes has so far given us the most satisfactory results.

Technique.

The illustration (Fig. 1) shows the lamp which we employ. It consists of two small metal pillars bracketed upon an insulating slate base. The pillars carry the horizontal arms upon which electrodes, water-cooled in the manner devised by Bang, are screwed. These arms can be approximated to each other by means of thumb-screws. They consist of an outer tube within which runs a smaller inner tube serving as inflow for the cooling water which returns by the outer tube.¹⁵ The arc is made by an electric current of 5 to 7 ampères with a voltage of 30 to 35 volts. The cooled electrodes give a perfectly cold arc light whose action is entirely free from any heat effect. In exposing an inoculated plate the lid is removed and the agar surface is directly exposed to the arc at a distance of about 6 cm. Upon the Petri dish is placed a sheet of blackened metal (or cardboard) in which an oblong window has been cut. By means of another sheet of blackened metal the window, which is at first fully open, is gradually closed. The different exposures given along the strip of window may with advantage be 30, 60, 90, 120, 150, 210, and 240 seconds, with a current of 7 ampères and 30 volts. In making such a plate from 0.5 to 1 c.c. of faeces are broken down in 2.5 c.c. bouillon and allowed to stand for about two hours. Two or three large

¹⁵ An apparatus which will be quite adequate for the purpose can be made at a comparatively small cost.

drops are then taken from the upper part of the fluid (preferably after brief centrifugalisation) and spread over the surface of an agar plate in the manner already described. The plate, which should be distinctly moist, is then subjected to the action of the arc light as already described, and incubated with the agar uppermost.

The method has been tested on mixtures of *B. typhosus* and *B. coli* in the following proportions: 1 to 1, 1 to 10, 1 to 20, 1 to 30, 1 to 50, 1 to 80, 1 to 100, 1 to 150, and 1 to 200. In every case where there were not more than 50 *B. coli* to each typhoid bacillus numerous isolated colonies of the latter were always found on some portion of the exposed area of the plate. Where there were more than 50, but fewer than 200, *B. coli* to each *B. typhosus* a few colonies at any rate of the latter have almost always been discovered on the plate. Indeed, in one experiment in which there were at least 500 *B. coli* to each *B. typhosus* a few isolated colonies of the latter were recovered. The colonies of *B. coli* on the exposed portion of the plate are well developed, whitish, and opaque, while those of *B. typhosus* are tiny, dewdrop-like, and quite transparent after 18 to 24 hours. From the latter streaks are made on the surface of plates of MacConkey's medium, Endo's medium, and ordinary agar in the order named with a once charged needle in order to confirm the diagnosis. The resulting growth is subsequently submitted to the usual tests.

The plate shown in Fig. 2 is from an experiment in which there were 50 *B. coli* to each *B. typhosus* in the mixture used for plating. The large colonies along the exposed strip are colonies of *B. coli*, while the numerous small colonies are colonies of *B. typhosus*. The density of the mixture used

FIG. 2.

Slide showing large colonies of *B. coli* and numerous small colonies of *B. typhosus*.

for plating is indicated by the complete opacity of the growth outside the limits of exposure to light. In view of the encouraging results of these experiments we have recently applied the method in the examination of the faeces of convalescents and suspected carriers. Of the cases examined seven have already yielded positive results by this method at the first examination, though the ordinary methods failed to afford any evidence of the presence of *B. typhosus* or *B. paratyphosus*. In five of the cases *B. typhosus* was isolated from the light plate and in the other two *B. paratyphosus* (B).

Obviously, the number of cases is at present much too small to justify a confident opinion regarding the ultimate practical utility of the method. But our results have up to the present been so satisfactory that it seems desirable under existing conditions to offer the method for the use and criticism of others, even though our evidence from actual cases is at present scanty.

A CASE OF

RUPTURE OF THE HEART IN A CHILD.

BY JOHN ANDERSON, M.B., C.M. GLASG.,

DIRECTOR OF CLINICAL LABORATORY, VICTORIA INFIRMARY, GLASGOW.

THE case is of interest, firstly on account of the age of the child, and secondly on account of the occurrence of a congenital stenosis of the coronary arteries and other manifestations pointing to inherited syphilis. The history was very meagre and unsatisfactory. The child, a girl 5 years of age, was, as far as we could learn, in good health up to the morning of her death. She had been somewhat neglected and was poorly nourished. About 9 A.M. on the morning of the child's death the woman in charge of her left the house, and the child was to stay in bed until she came back. On her return half an hour later she found the child had got out of bed and was sitting on the floor, looking ill and complaining of sickness. There was no history that the child had fallen out of bed. A little stimulant was administered, but as there was no sign of improvement the woman became alarmed and took the child to a neighbouring ice-cream shop, where she left her in charge, while she went in search of a doctor. The proprietor of the shop, afraid the child was dying, carried her to the nearest police office in the hope of obtaining the services of the police surgeon, but the child expired on the way. There was a history that eight weeks previously the child had had a fit, and a year ago she was in the parish hospital under treatment for eczema.

Necropsy.—The pericardium was distended with fluid blood. A hæmorrhagic area, 1 in. in length by $\frac{3}{4}$ in. in breadth, was noted on the anterior aspect of the heart along the line of the interventricular septum at its upper third, and also a small perforation within this area. The heart was removed and examined. It was normal in size, pale in colour except at the hæmorrhagic area. On opening the cavities a slight degree of dilatation was noted, but there was no hypertrophy of their walls except, perhaps, a small area in the left ventricle at the immediate apex, where the muscular substance was altered in appearance, abnormally pale, and somewhat translucent. The columnæ carneæ were unusually delicate and in places thread-like in character, and this condition was more noticeable in the case of the left ventricle.

The lesion which had given rise to the rupture was of remarkable character: a hæmatoma, $\frac{1}{2}$ in. in diameter, had formed in the wall of the left ventricle and septum at the place of discolouration above noted. Its cavity was filled with blood clot and its walls were ragged and granular. At its lower aspect it had ruptured externally into the pericardium, and a large probe could easily be passed through the aperture, which was situated $\frac{1}{2}$ in. from the base of the ventricle. The thinned inner wall communicated with the interior of the ventricle by a large and irregular aperture, which was continuous with an extensive rupture across the inner portion of the posterior wall of the chamber. The torn area almost encircled the ventricle, and reached as far as a point immediately beneath the position of the left auricular appendix. The laceration occupied a fair depth of the muscle, and the wall of the ventricle, when viewed by transmitted light, was quite translucent. The right ventricular wall was intact. The valves were of normal size and their curtains were healthy.

Examination of the coronary vessels showed a stenosis of the lumen of both arteries, and the descending branch of the left coronary artery was obliterated at the seat of the rupture and could not be traced beyond it. Above the rupture for a distance of $\frac{1}{2}$ in. its inner coat was discoloured, and a thin layer of fibrin was adherent to the intima. A small thrombus was present in the right coronary artery 1 in. from its origin. The venous sinus was dilated, and immediately beyond the valve a large thrombus was found in the great vein.

Drawing of heart showing (A) hematoma in septum and (B) rupture across posterior wall of left ventricle.

The lungs were non-adherent, and, apart from an area of congestion at the anterior edge of the upper lobe of the left lung, they were healthy. The larynx, trachea, and oesophagus were normal. The tonsils were slightly enlarged. The lymphoid nodes at the root of the tongue were unduly prominent, and the lymphatic glands on both sides of the neck and also the thymus gland were somewhat enlarged. The stomach was healthy. The lymphoid tissue of the small intestine was increased in amount and the Peyer's patches were enlarged. The mesenteric glands were enlarged and a number of them showed evidence of caseation.

The liver was of large size, firm in character, and slightly waxy in appearance. The spleen was somewhat enlarged and indurated with the Malpighian bodies unduly prominent on section. The right kidney was firm and congested, but otherwise it appeared normal on naked-eye examination. The left kidney was of normal size, more fibrous-like in appearance, and there was an area of pallor, 1 in. by 1 in., at its lower pole, suggestive of an old infarction. The suprarenals were small in size and the relationship of the cortex to the medulla was well maintained.

The brain and the other organs of the body were healthy.

Microscopical Examination of the Case.

Heart.—Paraffin and frozen sections were prepared and examined from different parts of the organ. There was no evidence of fatty degeneration, but the cells were dissociated over large areas in nearly every section examined and the striation of the bundles was to a great extent impaired. A

number of the cells showed the presence of small vacuoles. In the region of the rupture the appearances of advanced ischemic atrophy were noticed, and in other areas of the heart this condition was also observed, but to a less pronounced extent. In other parts of the heart, and especially in the area of the left ventricle in the vicinity of the apex, a distinct increase in the fibrous tissue was found, giving to the sections a highly cellular appearance. No gross areas of fibrosis were present. The small blood-vessels in the substance of the muscle were found to have a distinct thickening of their walls with cellular infiltration of their middle coats. The condition of the coronary arteries was that of a general stenosis. There was thickening of the inner coat noted in the smaller vessels. The thickening was patchy in its distribution, and large areas were normal. Inflammatory cells were seen in the neighbourhood of the vessel wall. Sections of the thrombosed vessels showed that this had taken place at affected portions of the inner coat.

Liver.—The sections showed in different places a distinct thickening of the capsule. There was a leucocytic infiltration between the liver cells of the nature of a pericellular cirrhosis, and the cells, although somewhat separated, were otherwise unaltered. Small aggregations of inflammatory cells were seen at different places within its substance. The fibrous tissue throughout the organ was generally increased and this increase was more marked in the portal zones. A distinct increase of fibrous tissue around the smaller arteries was also noted. Although miliary gummata had not been recognised in the naked-eye examination of the organ, one or two were met with in the microscopical examination of the sections, and their appearances were quite unmistakable.

Kidney.—The sections were prepared from portions of both kidneys. In each of them well-marked alterations of the nature of catarrhal and interstitial nephritis were found. Sections from the area of the left kidney, which presented the appearance of an infarction, showed a limited peripheral area of coagulation necrosis due to embolism. The changes in the kidney were more extensive in the cortical region, but the medullary portion was also considerably affected. Most of the glomeruli presented normal appearances. A number, however, showed increase of fibrous stroma, granular change of the epithelium, and partial loss of the capsular epithelium, while others showed evidence of shrinkage of the tuft, with a large space between it and the capsule. Congestion of the glomeruli was a marked feature of some of the sections, but in others it was present only to a slight degree. The changes in the convoluted tubules were the most marked feature of the specimen. The epithelium was swollen and granular, and desquamation of cells was abundantly present. A number of the tubules were dilated and extravasated blood was present in some of them. The straight tubules were much less affected, although desquamation of their cells was also noted. The stroma in the cortical region was increased in amount and highly cellular areas were interspersed between adjacent groups of glomeruli and tubules, giving a segmented character to the organ. The change in the interstitial tissue was chiefly of the fibroblast type, but areas of lymphocytes were also present. In the medullary portion of the organ the increase in the interstitial tissue was considerable and of the nature of an actual fibrosis. The fibrous tissue around some of the larger vessels was increased, but

thickening of the walls of the smaller arteries seen in the section might be interpreted as a normal condition of children (Carpenter).¹⁰

Spleen.—The capsule was thickened and the trabeculae within the organ were larger than the normal size. The pulp had undergone considerable alteration. The fibrous-tissue elements were increased and a leucocytic infiltration was also present. The walls of the smaller arteries were thickened and the muscular coat proliferated. The Malpighian bodies were not enlarged, but, if anything, they appeared smaller in size, and their undue prominence was due to the changes in the pulp of the organ.

The microscopical changes in the other organs were of no special significance.

Remarks.—Cases of rupture of the heart occurring spontaneously in children are very rare; and so far I have been unable to find an account of a similar case.

The interpretation which was placed on the case was that the child was the subject of an abnormal development of the coronary arteries. The vessels were unusually narrow, and further, the lumen was encroached upon in places by the areas of thickening in the inner coat due evidently to a syphilitic endarteritis. The hæmatoma in the septum was more than likely the result of the thrombosis in the descending branch of the left coronary artery, and represented really a dissecting aneurysm of the heart wall; and the case is comparable with that described by Lazarus-Barlow,¹ which, however, occurred in a man of advanced life.

The other view was that, as a result of the occlusion of the vessel and an insufficiency of the anastomosis, necrosis of the heart wall (infarction) had occurred. The endocardial blood had forced an entrance into the muscle, and, tearing its way with each successive beat of the heart through the weakened tissues (as suggested by Birch-Hirschfeld³), had reached the pericardium and perforated it. Although ischæmic atrophy was present in sections of the heart wall, this was more apparent at the apex of the ventricles and was by no means a feature of the sections which went through the actual ruptured tissue itself. Coronary artery disease is well recognised as a cause of myomalacia cordis, but ultimate rupture as a result of same, although it does occur, is by no means so common as one would expect. Steven,⁵ in an investigation of the coronary arteries and their effects on the heart, met with the condition only once in 102 cases of affected coronary arteries, although definite myomalacia was present in five. If microscopical examinations had been undertaken it is more than likely the lesser degree of heart softening such as was experienced in our sections would have been met with more frequently.

The other factors of our case bulk considerably in our interpretation of the condition—namely, that we were dealing with a heart which was weakened by inherited syphilis as well as by the thrombosis of the vessel. Evidences of syphilis were seen in the other organs as well as in the heart itself.

It has been held for long that inherited syphilis plays an important part in the causation of congenital heart disease. Most of the writers have dealt with the subject of the graver defects of the organ, such as patency of the interventricular septum and abnormalities of the great vessels, rather than with changes in the substance of the heart or lesions of the coronary arteries. The

recent advances in our appreciation of its rôle in the causation and its actual frequency have been strengthened from the clinical side by the study of such cases with the application of the Wassermann test either to the blood of the child or to that of the parents. Findlay and Robertson⁸ record the presence of a positive reaction in 9 out of 11 cases which they had observed. Browning⁹ (also quoted by Findlay and Robertson) gives Watson's results of a positive finding in 17 out of 25 cases of congenital cardiac disease, while Holt, on the other hand, records a distinctly adverse finding.

From the pathological side the finding of the spirochæta pallida in the heart muscle confirms the diagnosis. Warthin⁶ has found evidence of changes in the heart, due to syphilis, in a considerable number of cases. He has recognised an especial form of interstitial myocarditis due to the presence of the spirochæta pallida, and holds that such may exist independently of other signs or symptoms of congenital syphilis and may even be the only manifestation. He also regards the cardiac weakness produced by the presence of the *S. pallida* as predisposing to the subsequent other infections of the heart. He has found it associated with infantilism, hypoplastic constitution, or less severe forms of under development and as tending in later life to the production of fibroid heart and coronary sclerosis. In a later paper⁷ he discusses the primary tissue lesions in the heart produced by the *S. pallida*, and concludes that syphilis is one of the most important factors in the causation of cardiac disease. The appearance of the heart, he states, may not be such as would have been called syphilitic in the older interpretation of our knowledge of this disease. He also found it possible to demonstrate the presence of the spirochætes in the heart when it was impossible to demonstrate them elsewhere, and he regards their localisation in the heart as even more common than in the liver. In our case we were able to demonstrate their presence in the heart muscle, but only after careful examination, and their numbers were few. In the kidneys they were obtained with less difficulty and were more abundant, but in spite of the presence of miliary gummata it was impossible to say that they were present in the liver.

The histological change in the liver was such as is associated with congenital syphilis—viz., a pericellular cirrhosis. The changes in the kidneys were of the nature of the combined catarrhal and interstitial nephritis which has been met with in syphilitic infants (Carpenter and others¹⁰). Although it is possible that such a condition might have its origin in intestinal or other toxins, still, with the other factors of the case, we may regard the changes in them as an additional indication of the syphilitic nature of the disease.

A CONFERENCE on Our Food During War will be held at the Institute of Hygiene on Monday next, March 29th, at 3.30 P.M. Sir Malcolm Morris will preside, and well-known authorities will express their views.

ON THE MOVEMENTS OF THE NORMAL STOMACH.

By HUGH WALSHAM, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,

MEDICAL OFFICER IN CHARGE OF THE X RAY DEPARTMENT AT
ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE CITY OF
LONDON HOSPITAL FOR DISEASES OF THE CHEST;

AND

WALKER OVEREND, M.A., M.D. OXON.,
CHIEF ASSISTANT IN THE X RAY DEPARTMENT, ST. BARTHOLOMEW'S
HOSPITAL; LATE PHYSICIAN TO THE PRINCE OF
WALES'S HOSPITAL, LONDON, N.

CONSIDERABLE discussion has arisen and much diversity of opinion has been expressed by surgeons, anatomists, and radiologists concerning the configuration and changes of form of the separate segments of the stomach. It must be admitted that the stomach *in vivo* and in an active phase is a very different object from the same organ as seen on the operating table or in the post-mortem room. Bearing in mind the researches of Försell,¹ of Stockholm, and the various accounts given by radiologists of renown, we have adopted the following description as most convenient for our purpose.

1. Radiological Divisions of the Stomach (Fig. 1).

In the erect position the organ is syphon or J-shaped, consisting therefore of a vertical and of a horizontal component, the former constituting about

FIG. 1.

Normal stomach in erect position. F, Fornix. C, Corpus. S, Sinus or vestibule. A, Antrum. B, Cap of duodenum. D, Descending duodenum. N, Nipple. H, Heart. I, Ilium. U, Umbilicus. Ca, Cardiac constriction. mm, Angular constriction. oo, Antral constriction. P, Pylorus.

two-thirds of the whole. The angular notch (incisura angularis) on the lesser curvature marks the separation of the two. The vertical portion, sometimes termed the vertical stomach, is subdivided into (a) the fornix (fundus) lying above the oesophageal opening and as a rule containing air (air sac or reservoir); and (b) the corpus, which is vertical in the erect but slightly oblique in the recumbent position.

The pyloric or horizontal part (pars pylorica), as visualised on the screen, during certain phases of its activity only, is subdivisible into (c) the sinus or vestibule, (d) the antrum, and (e) the pylorus. The antrum may be found firmly contracted after death, and is then known as the pyloric canal.² During the concentric contraction of the antrum the latter becomes practically separated by a deep incisure from the sinus. This may be termed the antral constriction.

That part of the duodenum which first receives and temporarily retains the opaque chyme resembles the pyloric part in all essential features. It has been styled the cap or *pilleus ventriculi*,³ and represents the proximal half of the first portion of the duodenum. In reality the cap is to be regarded as a gastric annexe, and as such must be included in the description of the stomach.

2. Innervation of the Stomach.

The musculature of the stomach in association with its intrinsic nerve plexuses, ganglia, and extrinsic nerves manifests two chief properties—viz., (a) tone, and (b) peristalsis. Of these tone appears to be pre-eminently a function of the muscular fibre itself, and therefore primarily myogenic. Peristalsis, on the other hand, is dependent on the integrity of the myenteric plexus and ganglia situated between its muscular coats.

At the same time both tone and peristalsis are controlled and coördinated by the extrinsic nerves—the efferent fibres of the vagi and splanchnics. In addition to these connexions afferent fibres, associated with interoceptors lying within the mucosa and between the muscular layers, run from the submucous and myenteric plexuses, in the vagi and splanchnics, to the cord and medulla (viscero-motor and viscero-inhibiting centres), proceeding upwards by synapses and relays to the general sub-conscious emotional centres of the optic thalami.⁴ In the absence of the higher consciousness these centres probably exert their influence by connexions with the corpora striata. Furthermore, both tone and peristalsis lie under the influence of the highest emotional states—exaltation and joy, anger and fear, worry and grief—the loci of which are presumably situated within the cerebral cortex. The centrifugal paths will run either through the basal ganglia or direct to the visceral medullary centres.

The gastric mucosa is endowed with protopathic sensibility (heat and cold) and with protopathic appetite sensibility by nerve-twigs running into it from the submucous plexus.⁵ The stimulus for appetite appears to be the secretion of acid (0.5 per cent.). The sensory apparatus for hunger apparently lies between the muscular layers, and is stimulated by a certain type of contractions of the empty stomach (hunger contractions).

3. Technique and Description of Movements.

The outlines and activity of the stomach become visible when 10 ounces of an emulsion or fine creamy suspension of 2–4 ounces of bismuth subcarbonate or oxychloride, made with milk or water, are administered; 1½ ounces of lactose may be mixed with the solution in order to make it more palatable.⁶ It is preferable to select a sparely nourished individual, and the canalisation should be observed in the erect position.

If a small quantity, about 1 ounce, be first swallowed the bismuth sometimes may be seen to run down as a narrow longitudinal band direct to the sinus, filling the *canalis gastricus*,⁷ which lies along the lesser curvature. It is surmised that the oblique muscular fibres may temporarily convert the gastric groove along this curvature into a gastric canal or arcade. However this may be, when tone is normal the bulk of the food is held up for a time beneath the air reservoir and only gradually canalises the corpus, reaching the sinus gradatim.⁸ When the repletion of the pars pylorica is complete the recumbent position is assumed, and the patient reclines on the right side for a few minutes in order to fill the duodenum.

Under these circumstances the movements may be seen to commence on the greater curvature of the corpus just below the cardiac notch (Home's point), and they are propagated as a slowly recurring series of annular constrictions becoming deeper and more pronounced as they approach the pylorus. In Fig. 2, A, as many as four successive waves may be counted simultaneously. The condition 6 seconds after A is represented by B; after 14 and 20 seconds by C and D respectively. At D the stomach has practically reached the stage of A, and the antrum has

FIG. 2.

After Rieder. Changes of form during contraction. A, Antrum. S, Sinus. 1, 2, 3, 4, Waves of constriction.

just re-expanded preparatory to the commencement of a new systole. This lasts apparently about 12-14 seconds, and is followed by the stage of diastole or (active?) dilation which occupies 6-7 seconds.

During the diastole chyme will be drawn from the sinus and, if the pylorus be open, pancreatic juice from the duodenum. If the pylorus be shut contraction of the antrum will drive the chyme backwards into the sinus in an axial stream. During diastole the most essential change in outline of the pars pylorica results in the formation of a new antrum. The antrum is therefore of supreme importance in the comminution and, the pylorus being open, the propulsion of the chyme. It has accordingly been termed the *motor* of the stomach. It may be compared to the ventricle of the heart, the sinus to the auricle, and the cap to the aortic bulb. Obviously peristalsis is *par excellence* the function of the pars pylorica, and in particular that of the antrum.

4. Action of the Vagi and Splanchnics (Fig. 3).

At the present time there is no general consensus of physiological opinion as to the action of these two nerves on the gastric outlets. It appears to vary in different animals. We know that they perform opposite functions generally,^{8a} and that the effects of stimulation of the splanchnics resemble those of adrenin.⁹ We may therefore postulate the existence of an antagonistic hormone, possessing intimate relations with vagal activity. Extract of pituitary,¹⁰ after a slight inhibition, produces a powerful and persistent augmentation with increase of the rhythmical movements of the stomach. Adrenin appears, on the other hand, to diminish the excitability of the vagus, although the precise conditions of its occurrence have not yet been ascertained.

Moreover, there appear to be differences in individuals as to the relative excitability of the nerves. Some clinicians have described the conditions of vagal and sympathetic hypertonia¹¹ according as one or the other nerve appears to possess an ascendancy in the production of symptoms. In the former (by far the more numerous) the oculo-cardiac¹² reflex of the trigeminus is accompanied by a diminution of cardiac beats, in

the latter by an increase. Vagopathic individuals would be more likely to suffer from gastric hyper-tonus, antral spasm, hyperacidity, and from spasm of the duodenal cap. The splanchnopathic subject might exhibit an inclination to sluggish digestion, delay of gastric evacuation, and a tendency towards atony, pyloric spasm, and gastric ectasia. Individuals in whom cutaneous stimulation refuses to elicit the cutaneous vagus reflex (*vide infra*) may belong to this class; although fear and anxiety in both categories by stimulation of the splanchnics would induce a similar failure.

We know that stimulation of the vagus dilates the cardiac opening of the oesophagus, and the opposite condition of cardiospasm may be due to vagus inertia, inhibition, to the activity of local ganglia or to the action of the sympathetic. A better term for the latter condition is cardiotonia. The designation "achalasia" has been recently proposed.¹³

The vagus also exerts a tonic effect on the walls of the stomach, stimulates peristalsis of the organ and of the cap, and secretion of the gastric glands. The splanchnics produce a diminution of tone and a decreased peristalsis.

FIG. 3.

Vg +, Vagus contraction. Vg -, Vagus relaxation. Sp +, Splanchnic contraction. Sp -, Splanchnic relaxation.

With regard to the action on the pylorus the general effect of the vagus in man is probably to relax and that of the sympathetic to increase its tone.¹⁴ Similar results may be inferred as to the action of the nerves on the cap, and on a problematical physiological sphincter which separates it from the distal duodenum.

5. Gastric Reflexes.

It has been suggested that the difficulty or delay of canalisation of the corpus is not due to a necessary distension of its walls (assuming that the empty stomach has no capacity), but to an oesophageal reflex¹⁵ which controls the oblique muscles and increases their tone. It is more probable that the reflex may arise from the gastric mucosa itself. But the appearances observed when the recumbent position is adopted throughout seem to negative this hypothesis.

At times the entire stomach passes into a quiescent passive state. This may be produced by repletion of the small bowel acting reflexly by way of the splanchnics. Impulses may pass along these nerves from the highest emotional centres (anxiety and fright) which induce a similar condition of gastric stasis.

Interesting facts have been recorded with regard to the hungry stomach in dogs.¹⁶ With the nerves intact all mechanical and chemical stimulation of the intestinal mucosa cause inhibition of gastric tonus and cessation of hunger contractions. Pure gastric juice and HCl (0.5 per cent.) cause the quickest and longest inhibition. Moreover, sodium carbonate itself has a slight inhibitory effect. When the vagi and splanchnics are divided similar results follow, but the latent period is much prolonged and the degree of inhibition is considerably diminished. This inhibition of tone and contraction therefore involves both long or central, and short or local reflex paths. The longer reflexes are dominant. It is uncertain how far one can apply the results to the digesting stomach and to man, since it seems justifiable to assume that the vagus itself has gradually come to participate much more freely in these reflexes, and that in the normal stomach such excitation may often result in hypertonus and hyperperistalsis of that organ. It is also noteworthy that stimulation of the gastric mucosa itself, in the above experimentation, by alkalies or acids, and by the secretion of gastric juice produces a depression of the hunger contractions.

Reflex activity on the part of the *vagus* may be induced by stimulation of the costal margins of either side by means of a gentle sliding movement of the fingers upon the skin.¹⁷ Sometimes the appendicular area is equally efficacious. After a variable interval—10 to 30 seconds or longer, in the meantime the stimulation being continued—peristalsis of the stomach commences, and by constant repetition of the excitation a complete evacuation of the contents is possible. The most favourable time is about three hours after food. With a binaural stethoscope applied over the site of the duodenum the flow of chyme is plainly audible. On the fluorescent screen at times a fleeting evanescent wave of dilatation is seen to precede the peristalsis, thus apparently bringing the movement into line with the peristalsis of the small bowel and the law of the intestines.¹⁸ In other words, it becomes a true peristalsis. It does not follow that a relaxation of the pyloric sphincter of sufficient force to open it precedes the arrival of each wave of contraction. In the early stages of gastric digestion the stimuli are subliminal and the summation of several is necessary to produce this effect.

6. The Role of the Acid Secretion: Duodenal Reflexes.

Since the gastric motility is quite as vigorous when the carbonate is substituted for the oxychloride it is unnecessary to ascribe to the acid any serious influence over the function of peristalsis. It has also been accepted that the presence of acid on the gastric side relaxes the pylorus, whilst on the duodenal side acid evokes a reflex which shuts the sphincter. Inasmuch as the cap and antrum are physiologically essentially similar it is difficult to subscribe to this theory. Moreover, it does not explain many of the facts.

If the statements of Boldyreff¹⁹ are verified the play of the pylorus is by no means a simple matter. It appears that the alkalinity of the pancreatic secretion is normally required to neutralise the acid (0.5 per cent.), and it seems probable that the juice enters the stomach itself to accomplish this purpose. Boldyreff ascribes this influx to an anti-peristalsis on the part of the duodenum. Have we any evidence of this in man? It is common to see a morsel of bismuth moving towards the jejunum

suddenly stop in the middle of the descending duodenum and turn back for a moment before resuming its course. Is this due to an anti-peristaltic wave (anastalsis) of the duodenum, or is it a suction effect on the part of the dilating antrum with an open pylorus? The antrum usually contracts so powerfully that its opaque contents disappear entirely for an interval of time, and the succeeding dilatation is probably no less energetic. Prolonged observations are necessary in order to discriminate. Both events may participate. The theory of duodenal reflex closure and its absence in ulcer of the duodenum is at least a subject for argument and difference of opinion.

In so-called duodenal irritation the whole process of gastric digestion is more speedy than in the normal. It is not due to duodenal irritation; rather is it a sign of reflex vago-gastric excitation. Afferent impulses from near and distant areas, as the gall-bladder (calculi), appendix (chronic appendicitis), colon (colitis, colica mucosa, and certain forms of constipation), the kidney (nephroptosis, calculi), and many other even extra-abdominal situations,* are carried to the medulla and reflected along the vagus to the stomach and duodenum. The duodenal irritation is the effect, not the cause. Any individual with hypertonus of the stomach, rapid gastric evacuation, with lively antral peristalsis and exalted pyloric display, is potentially liable to ulceration of the duodenum. The outcome depends on the integrity and reactive capabilities of the pancreas. The increased gastric phenomena invoke a greater production of secretin²⁰ and a heightened reflex secretory excitation of the vagal branches supplying the pancreas.²¹

Further investigations are necessary before we can fully comprehend the intricate behaviour of the pylorus and the manifold activities of the antrum and duodenum. Also the relations between ulcer of the lesser curvature and the formation of the lesser gastric canal, and between splanchnic irritation and ulcer of the pylorus, are suggestive but so far speculative.

Achylia gastrica and senile dyspepsia with deficit of gastric juice may result from a diffuse fibrosis affecting the gastric glands and pylorus. In old age, moreover, there supervenes a condition of atony in the sphincters generally which leads to diminished efficiency. But an extended discussion of the opaque stomach and duodenum in disease would lead us far beyond the limits of this communication.

BERI-BERI AT FALMOUTH.—At the last meeting of the Falmouth and Truro port sanitary authority the medical officer of health, Dr. G. E. Lanyon, reported that several vessels had arrived with cases of beri-beri on board. They were chiefly vessels engaged in whaling. Investigation of the patients gave no satisfactory explanation.

A NOTE ON

CERTAIN PECULIAR CRYSTALS FOUND IN THE CEREBRO-SPINAL FLUID FROM A CASE OF SEPTIC MENINGITIS.

BY W. W. D. THOMSON, B.A., B.Sc., M.B., D.P.H. BELFAST,

RIDDILL DEMONSTRATOR OF PATHOLOGY, QUEEN'S UNIVERSITY, BELFAST; PHYSICIAN AND CLINICAL PATHOLOGIST, MATER INFIRMORUM HOSPITAL, BELFAST.

ON Feb. 16th, 1914, I received from Dr. A. Gardiner Robb, medical superintendent of the Belfast Fever Hospitals, a sample of cerebro-spinal fluid drawn from a case clinically resembling cerebro-spinal fever. Further examination of the patient, a girl aged 18 years, discovered that there was present a chronic otitis media, which had probably set up a septic meningitis. The patient died soon after the lumbar puncture. Permission to hold a post-mortem examination was refused.

The cerebro-spinal fluid on centrifugalisation yielded a copious deposit. This deposit consisted of pus cells of the neutrophil polymorphonuclear variety, along with large numbers of peculiar crystals. (Fig. 1.) The bottle in which this fluid was sent to me had been most carefully sterilised before use, so that there could be no question of contamination. The crystals when examined in a hanging-drop preparation seemed in some cases to be intracellular. They varied greatly in size from

FIG. 1.

Deposit from cerebro-spinal fluid containing crystals. $\times 860$.

2 to 10 μ . Mr. A. R. Derryhouse, D.Sc., F.G.S., lecturer in geology, Queen's University, Belfast, kindly examined the crystals and reported as follows:—

The crystals are elongated and appear somewhat rounded at the ends. They are colourless and transparent, and possess a refractive index greater than that of the clove oil (1.53) in which they are mounted. Most of them contain a central nucleus or spot (A, Fig. 2), which appears to have crystal outlines and sometimes gives the effect of zonal structure. This effect may be due to the existence of pinacoid facets flanked by one or more pyramid faces (C). There are also a few twin crystals (D). The crystals are strongly doubly refracting, and the extinction

is straight which places them in either the tetragonal, hexagonal, or rhombic system. From the general form I am inclined to think they are rhombic.

These crystals were found to be soluble in dilute acids (organic and inorganic) and alkalies, and in acid spirit. They were insoluble in alcohol, ether, chloroform, acetone, or boiling water. They were

FIG. 2.

Forms of crystals.

unstained by Gram's method, eosin, methylene blue, carbol-fuchsin, iodine, or collargol. No further crystals were yielded on evaporating down the supernatant fluid left after centrifugalisation.

I attempted to obtain some information as regards the chemical composition of these crystals, apart from their solubilities; but from their small size and the small quantity available this part of the examination was difficult. The fact that these crystals crystallised out from the cerebro-spinal fluid itself renders it highly improbable that chlorides are present; sulphates are only present in such very minute quantities in the serous fluids that their presence is most unlikely; oxalates are insoluble in acetic acid, while these crystals are soluble in acetic acid. Thus it seemed to me that phosphoric acid was the acid radicle probably present. In examining for phosphates I followed A. B. Macallum's method¹ for the detection of phosphates microchemically. Films of the crystals were prepared on coverslips, fixed in alcohol, and placed in a nitric acid solution of ammonium molybdate for 24 hours at a temperature not exceeding 35° C. The film was washed with dilute nitric acid and water, and then placed in a freshly prepared 4 per cent. solution of phenylhydrazine hydrochloride. (This latter reduces the phospho-molybdate throughout the preparation, whether it be derived from inorganic or organic compounds of phosphorus, to a greenish-blue coloured compound.) After reduction the preparation was thoroughly washed with water, dehydrated, cleared, and mounted in balsam. As a control I at the same time and by the same method examined films of the coffin-lid crystals of ammonium-magnesium phosphate obtained from urine. I found in both cases that the crystals became disintegrated; but whereas in the latter case the films after treatment with phenylhydrazine hydrochloride became blue-green, the films with the crystals from the cerebro-spinal fluid remained colourless, nor could I distinguish microscopically any colouration save a faint yellow. Thus the chemical examination, repeated frequently, seems to negative the presence of phosphoric acid.

While it seems improbable from the solubilities above mentioned that these crystals consist of a salt of choline, Rosenheim's test² was carried out to throw light on this point. This test depends on the formation of brown hæmin-like crystals of choline periodide when substances containing choline are treated with a strong solution of iodine in potassium iodide. This test gave me a negative result.

² Otto Rosenheim: Choline in Cerebro-spinal Fluid, Journal of Physiology, vol. xxxv., pp. 465-472.

These crystals resemble the Charcot-Leyden crystals and Böttcher's sperm crystals in the fact that they are doubly refractile and soluble in dilute acids and alkalies. They differ, however, by being probably in the rhombic system, whereas the Charcot-Leyden crystals are octahedral and Böttcher's crystals are hexagonal.³ The Charcot-Leyden crystals are soluble also in hot water, stain with eosin (as do also the sperm crystals⁴), and are accompanied by an eosinophilia as in asthma. Böttcher's crystals have been demonstrated by Pöhl⁵ to be the phosphate of an organic base (spermin). I failed to demonstrate the presence of phosphates in the crystals which I have described. Nothing definite is yet known as to the chemistry of the Charcot-Leyden crystals.

Scheiner considers that Charcot's crystals and Böttcher's sperm crystals are identical, notwithstanding Cohn's claim that these crystals differ crystallographically; the crystals described in this article seem quite distinct from either.

FIG. 3.

Microphotograph of streptothrix. $\times 1120$.

The deposit, after careful microscopical research, showed a few extracellular Gram-positive cocci and an occasional large rod-shaped bacillary form. There was no evidence of meningococci. On culture on agar I obtained a growth of staphylococci and a few much larger colonies, round and opaque, which grew into the agar, having a cup-shaped base. They clung tenaciously to the culture medium, and it was exceedingly difficult to break the colony down so as to obtain a fine emulsion. On staining these colonies were found to be composed of a Gram-positive streptothrix, a microphotograph of which is shown in Fig. 3. I consider the bacillary forms seen on direct examination as probably small bacillary filaments of this streptothrix. An enforced absence from the laboratory prevented a further examination as to the cultural and pathological characteristics of this organism.

As I can discover no account of crystals such as I have described being previously found in the cerebro-spinal fluid I thought that this pathological finding was of sufficient interest to report.

I have to thank Professor W. St. Clair Symmers, professor of pathology, Queen's University, Belfast, for his assistance in searching the literature of the subject; Dr. J. A. Milroy, lecturer in biochemistry, for his advice in the chemical examination of the crystals; Dr. Derryhouse for examining the crystals morphologically, and Dr. H. P. Malcolm, demonstrator of anatomy, for the trouble he took in obtaining the microphotographs illustrating this article.

Belfast.

A CONTRIBUTION TO THE BACTERIOLOGY OF THE URINARY TRACT IN CHILDREN.

BY ATHOLE ROSS, M.D. CANTAB., M.R.C.P. LOND.,
PATHOLOGIST TO THE EAST LONDON HOSPITAL FOR CHILDREN.

THIS paper deals with 106¹ catheter samples of urine which have been fully examined bacteriologically. At the outset it seemed advisable to make a bacteriological investigation of urines obtained from normal children. Although there are obvious objections to catheterisation in the case of healthy children, the difficulty is partially overcome by making use of the hernia and cleft palate cases awaiting operation in the surgical wards. A series of 19 catheter urines was in this manner collected. All specimens were collected by competent individuals and every possible precaution taken as regards instruments, patients, hands, and culture media, which last were incubated previously to use. Of these 19 specimens 11 were sterile after from 48 to 72 hours' incubation, whilst 8 grew an organism which was invariably a white staphylococcus.

Broadly speaking, this particular white coccus was found to acidify litmus milk (often only after some days' incubation) but not to clot it; to grow slowly on gelatin without liquefaction; to have no effect on neutral red broth anaerobically, and to acidify maltose. No change ever occurred in mannite, and a white colony was obtained on agar. Most likely the coccus is present in that portion of the urethra which is inaccessible to cleansing from the outside. In 5 out of the 8 positive cases the first broth tube used to receive the urine grew the coccus, while the second one employed remained sterile. This points to the presence of small numbers of organisms, and further suggests that they are picked up by the catheter in the deeper portions of the urethra and meatus and washed down through the eye of the instrument.

Infection by the *Bacillus Coli*.

In all instances the catheter specimen was collected in a sterile tube, transferred thence to broth and McConkey culture tubes, and 24 hours later neutral red bile salt agar and agar plates were made. All the coli organisms produced acid and gas in McConkey, maltose, mannite, lactose and dextrose, grew on gelatin without liquefaction, and formed a red colony on neutral red bile salt agar. The atypical behaviour of these bacilli is seen in regard to the production of indol, the fermentation of cane sugar, and the effect produced on litmus milk. These reactions in 43 different strains of urinary *B. coli* are summarised below.

The indol reaction was found present with great frequency after the organism had been grown three or four days in peptone water and using the paradi-

¹ At the time of writing the total has now reached 157, but the additional cases merely bear out the general results here recorded.

methyamidobenzaldehyde method. Possibly the absence of indol formation, so frequently recorded in *B. coli* isolated from the urinary tract, is due to the use of the less satisfactory nitroso-nitric acid test. All the litmus milk cultures were observed for a week or ten days, if no clot formation had occurred earlier.

Summary of Reactions.

Test.	No. of strains tested.	Result.
Action on litmus milk	43 ...	{ Acid and clot in 26; acid only in 17.
Peptone water—indol reaction ...	34 ...	{ Indol present in 33; no indol in 1.
Action on cane sugar... ..	27 ...	{ No change in 17; acid and gas in 10.
Action on neutral red broth	11 ...	All showed reduction.

The channels of infection.—For a discussion on this point reference must be made to papers by Hale White in THE LANCET and Nabarro in the Practitioner. Infections of the urinary tract by the colon bacillus may be roughly divided into: 1. Cases of colon bacilluria which are entirely latent or else present mild symptoms only, such as a certain degree of pyrexia. In such examples only a few leucocytes are present in an acid urine, although it may be teeming with bacilli. 2. The cases of frank pyuria with symptoms of cystitis, or it may be of pyelitis. Such patients may be the subjects of tuberculosis affecting the urinary tract, and generally show a considerable amount of pus in an acid urine. Most of the cases dealt with here belong to the first category, and only some half-dozen or so to the second.

Out of 43 cases of *B. coli* infection 7 were males (16·3 per cent.) and 36 females (83·7 per cent.). I favour the view that the infection is from without and due to a direct passage of the organisms from the anal orifice to the vulva, and thence upwards via the urethra to the bladder, &c. At the same time this hypothesis, while explaining the majority of instances of infection, will not cover them all, and the other possible routes cannot be entirely ruled out as some authors appear to think. The bulk of the patients were girls suffering from acute summer diarrhoea (with or without the added complication of oedema); in such, bacilli of the colon group and its congeners are known to be present in a state of exalted virulence within the alimentary canal. While it is not easy to say what particular organism of the typho-colon or the salmonella groups may be the cause of any case of acute enteritis in a child, it must be allowed that the colon bacillus, when present alone or in combination with some of the allied organisms, might easily gain entry to the bladder by direct extension in the female. Provided that the patient's resistance—i.e., the natural immunity—to the entry of pathogenic germs has been impaired by some intercurrent disease, this direct extension hypothesis would cover a majority of the female cases. The impairment of resistance seems to be an important factor, and it would help to explain the occurrence of colon bacilluria which I found in the following list of cases: diphtheria, lobar pneumonia, relapsing pneumonia, pneumonia with measles, migraine, tuberculous peritonitis complicated by measles, and miliary tuberculosis. Of course, a colon bacilluria is far and away most common accompanying some infective process in the alimentary tract, but it is not confined by any means to such cases. As regards the blood stream as a possible channel of infection, although many observers (including myself) have failed to get positive results from blood cultures, there is some experimental evidence

in its favour, and Panton has recently shown that colon bacilli may be cultivated from the blood stream in certain acute infective conditions.

Examination of films.—An examination of stained films from the centrifuged deposit serves sharply to mark off the colon carrier from the pyuria cases with their very abundant leucocytes. Thus out of 40 cases of colon infection (17 of which were instances of acute summer diarrhoea complicated by oedema) from the medical wards, only 1 showed a true pyuria, while 2 others revealed numerous polymorphonuclear leucocytes with a slight deposit on centrifugation. Nineteen examples showed a variable number of bacilli, scanty leucocytes, or merely a few mononuclears; 6 showed neither cells nor organisms in the film, and the remaining 12 bacilli alone with no cells. It was usual in the colon carrier to find few or many bacilli associated with very scarce polymorphonuclear leucocytes.

Vaccine treatment.—The autogenous vaccine was used for 3 patients with bad pyuria on the surgical side. In all the bacilluria persisted, but the amount of pus was diminished and the clinical state underwent an improvement, which had not been noticeable previous to the use of vaccines. An examination for tubercle bacilli was made in all these cases, but none were found. Among the patients in the medical wards vaccine treatment was but little employed, and in the oedematous cases 3 to 5 minims of 1 in 1000 adrenalin solution either orally or hypodermically was particularly successful; in numerous instances alkaline treatment was used with good effect. In 24 patients the urine was repeatedly examined by culture to determine if it was sterile after the children had been some time under treatment. In 10 instances there was no bacilluria when the children left hospital, and in 4 not even a staphylococcus was grown.

It was not my experience to find that the bacillus present commonly underwent alteration during the child's stay in hospital. Five examples did, however, occur in which a *B. coli* gave place to a bacillus proteus or the reverse sequence obtained. The average stay in hospital of those children whose urine became culturally bacteria free was from three to six weeks. Those patients in whom the bacilluria persisted to some degree all left the medical wards practically well and with no pus in the urine. This contrasts with those few cases of the surgical type (and the possibility of a tuberculous infection in the background) referred to earlier in this paper.

In this investigation particular interest has centred round certain cases of acute enteritis in children, complicated by oedema, the majority of which were found to be subjects of a colon bacilluria. There is apparently no obvious connexion between the bacilluria and the oedematous state. 1. The colon bacillus may be cultivated from the urine of many severe cases of summer diarrhoea uncomplicated by oedema, as was demonstrated bacteriologically on numerous occasions. 2. A state of lowered resistance to infection, due to diseases other than acute enteritis, may afford an opportunity for the colon bacillus to effect a lodgment in the urinary tract. In four of the enteritis cases, which terminated fatally, neither necropsy nor the microscope revealed any renal or cardiac condition to which the oedema might be attributed. Naked eye, the kidneys showed very little, while microscopically there was merely cloudy swelling in the protoplasm of the cells lining the spiral and convoluted tubules.

One patient in the surgical wards presented renal changes of more interest. The case was pyonephrosis with colon bacilluria, and death was due to general peritonitis. Tubercle bacilli were not found in the urine, and there was no post-mortem evidence of tuberculosis. Both kidneys showed punctate hæmorrhages and were riddled with small abscesses. While the glomeruli were little affected in the convoluted tubules many cells had lost their nuclei, and the protoplasm was granular, broken down, and destroyed. The abscesses consisted of a limiting membrane of compressed renal epithelium bounding a collection of inflammatory cells, which was broken down into a granular detritus at the centre. These cell collections included a fair number of polymorphonuclears, but mononuclears predominated. In this group are included two cases of bacilluria due to Day's paracolon organism and one to the bacillus of Gaertner. Once also a case of enteric fever was detected through a bacteriological examination of the urine.

In three or four instances a bacillus which I am unable to identify was isolated. It was non-motile, Gram-negative, never liquefied gelatin, formed a white colony on neutral red agar, and gave no indol reaction. It grew without producing either acid or gas in maltose, mannite, lactose, dextrose, dulcitol, McConkey, cane sugar, raffinose, and salicin. Some authors speak of a variety of *B. coli* termed "non-aerogenes." Its pathogenicity to animals has not been tested.

Infections due to B. Proteus Vulgaris.

Braxton Hicks, Dudgeon and Ross have all recently drawn attention to the rarely manifested pathogenic powers of this saprophyte. There are 19 instances in which *B. proteus* was cultivated from a catheter specimen. One of the patients had pyuria and quite a sharp attack of cystitis, but in none of the others were there any clinical symptoms pointing to the urinary tract. In this total were 8 cases of summer diarrhoea complicated by œdema, 3 others not so complicated, and the remainder included such varied disorders as constipation, bronchopneumonia, measles, and appendicitis. As regards sex distribution 10 were boys and 9 were girls, which is in contrast to the results obtained for *B. coli*. It was found that the cultural reactions of this group were extremely variable in the litmus sugar media; indeed, the chief diagnostic point lay in the isolation of a Gram-negative bacillus with the power of liquefying gelatin. Five strains gave an indol reaction out of 12 tested. Beyond the fact that this bacillus was found in certain cases of acute enteritis, the majority of which had œdema as well, it was of no interest.

The Presence of Staphylococci.

Staphylococci alone were isolated 25 times from pathological urines. The diseases concerned included œdema after enteritis (4), enuresis (2), uncomplicated acute enteritis (1), and other examples were multiple arthritis, acute mastoid, cystitis, acute nephritis, purpura, spasm of the sphincter vesicæ, pneumonia, and pleurisy.

The fact that staphylococci only were cultivated from four cases of œdema after acute summer diarrhoea and vomiting shows the need for caution in connecting this symptom in any way with the bacteriological state of the urine. As a rule, there is no reason to attach any importance to the presence of urinary staphylococci which give a coarse white colony on agar. The circumstance that staphylococci may be cultivated from control urines

quite discounts their value as etiological factors in pathological conditions, as does also the great diversity of the pathological states in which they are found and their low degree of virulence. Some attempt was made systematically to examine these cocci upon a few media with the following results:

Gelatin slope...	19 strains : no liquefaction. 6 strains : liquefaction.
Litmus milk...	13 strains : acid. 10 strains : acid and clot. 2 strains : no change.
Maltose...	All acid.
Mannite...	22 strains : no change. 3 strains : acid (usually slight).
Red broth...	Out of 11 strains tested reduction occurred in 3.

In 7 examples which clotted milk there was partial or complete decolourisation as well. All these cocci gave a white colony on agar. Most of the cultures were kept a week under observation at 37° C. Lactose was acidified on every occasion when used. Raffinose, salicin, and inulin were also employed, but the results were too inconstant to be of any value. Out of the 3 strains attacking mannite 2 only produced slight acid formation after five days' incubation.

On reference to the table given by Gordon on p. 144 of his translation of Abel's "Handbook of Bacteriology" it was found that out of these 25 urinary white staphylococci 3 strains gave the reactions of *S. epidermidis albus*, 11 those of "a staphylococcus sometimes found on the skin," and 10 other strains were slightly atypical according to the Gordon tests. Most of these atypical examples conformed to the reactions of "a staphylococcus sometimes found on the skin," except that a clot was produced in litmus milk, usually after some days' incubation, and not in any case sooner than three days. The net result would therefore appear to be that these urinary white staphylococci are closely allied to the white staphylococcus of the skin. If the Gordon tests are applied with care and an absolute mechanical uniformity in results is not expected, they are decidedly valuable as a help in classifying the staphylococci.

In his researches on the bacteriology of the urine in rheumatoid arthritis Warren Crowe has isolated with great constancy an organism which has now finally received the name of *Micrococcus deformans*, and the cultural characters of which are now pretty well known. Outside the group of diseases to which Crowe has directed his attention I am not sure that the *M. deformans* is commonly found in the urine, but as regards the bacteriology of the urine in the class of case to which Crowe has devoted himself I have no experience, and must refer those interested to the original papers.

Shortly after I became acquainted with this new work a sample of urine from a child suffering with rheumatic pains, slight sore throat, and some tenderness together with swelling of the joints, was sent for examination. I communicated with Dr. Crowe, sending him the white staphylococcus isolated. He very kindly worked it out for me and we found that it was identical in cultural characters with *M. deformans* or staphyloid coccus A. From this point onwards all the urinary staphylococci obtained to the number of 14 were examined as to the nature of the colony produced on neutral red egg, with the result that only one proved to be *M. deformans*. The colonies from the remaining

13 examples on egg media were at first rose red, but soon had the appearance of a flat orange-coloured growth, which later on changed to pale cream or even to white after some days in the incubator. These growths were quite distinct from the flattened, deeply indenting rose-red colony proper to *M. deformans* and obtained in two of my cases. Crowe describes *S. albus* as rare in the urine and forming a vivid orange growth on neutral red egg. The use of neutral red egg seems to be the crucial test for the presence of *M. deformans*, as agar is useless for this purpose. Crowe hints that *M. deformans* may be a member of that group of white staphylococci which are encountered on the human skin. I had also come to a similar conclusion with regard to the white staphylococci isolated in the present series of urines after using the Gordon tests. Apparently the clotting and decolourisation of litmus milk² is not so sure a guide as the use of the neutral red egg medium, which was made up in accordance with Dr. Crowe's directions. The question requires further investigation, but at the same time some reasonable doubt may be entertained as to whether the *M. deformans* can be isolated so frequently from the urines of non-rheumatoid subjects, while it looks as if some variety of *S. albus* was fairly common.

In conclusion, I desire to thank collectively the staff of the East London Hospital for Children for permission to make free use of all their cases.

UNIVERSITY OF MANCHESTER.—An eventful winter session has now been brought to a close. In the Michaelmas term there were no lectures on Wednesdays and Saturdays, but with the new year in the medical school the usual routine of lectures was restored. The senior medical students have been doing yeoman service in the infirmary, where the scarcity of residents has been felt.—Professor A. E. Boycott has transferred his services to London, and the University has found a successor in Henry Roy Dean, M.D. Oxon., F.R.C.P. Lond., professor of pathology in the University of Sheffield. It has not yet been determined when the new professor will enter on his duties, whether during the summer term or in October.—The University has issued a first and as yet incomplete list of past and present members of the University who are serving with the colours. The total number so far known to be serving is 765, made up as follows: members of the staff (42): army, 12 commissioned officers, 4 privates; R.A.M.C., 26 commissioned officers. Past and present students (723): army, 331 commissioned officers, 238 privates; navy, 12 commissioned officers, 17 privates; R.A.M.C., including A.V.C., 111 commissioned officers, 14 privates. The University has to regret several losses, including Captain Frank Forrest, R.A.M.C.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on March 5th, Dr. W. JOHNSON HORNE being in the chair.

Dr WILLIAM HILL showed a female patient, aged 25, with an Angioma (bleeding polypus) at the anterior end of the nasal septum, for which eradication by surgical diathermy was proposed.

Dr. L. H. PEGLER showed X ray photographs illustrating the thoracic appearances in a case of Left Recurrent Paralysis associated with Mitral Stenosis. The patient (deceased), a Jewish girl aged 19, went to the Metropolitan Throat Hospital in July, 1914, complaining of hoarseness on waking and vocal disability since the previous January, due to paralysis of the left vocal cord, which was fixed. She was admitted to the Brompton Chest Hospital on August 11th under the care of Dr. W. C. Bosanquet, who lent the photographs shown. She died at home four days after her discharge, having developed all the symptoms of acute laryngitis. On admission the girl, who had suffered formerly from rheumatic fever, complained of cough, pain in the left breast, and shortness of breath. A long presystolic murmur was audible at the apex, with thrill. Posteriorly, some râles at the bases of both lungs. The temperature remained at about 100° F. all the time; no tubercle bacilli in the scanty sputum. Dr. Dundas Grant by direct bronchoscopy found no abnormal pulsation. Dr. S. Melville X rayed the thorax on August 17th and reported: "Heart enlarged, purse-shaped. Above the left border is a well-defined shadow more or less in situation of right ventricle. Aorta wider than normal." In the absence of a necropsy the intimate relationship between the cardiac conditions and the recurrent paralysis must remain a matter for speculation. Sir StClair Thomson in his book, said Dr. Pegler, quotes Ortner as the first to describe this rare complication of mitral disease, and states that 37 more have been published since, but the instances are few in which the causal relationship has been established post mortem.—Dr. F. DE HAVILLAND HALL stated that he had seen a case in which he believed that the paralysis was caused by dilatation of the left auricle.—Sir STCLAIR THOMSON and Dr. DUNDAS GRANT pointed out that there were very few cases in which it had been proved that the paralysis was due to direct pressure of the heart.

Dr. PEGLER also showed four specimens of Superior Maxillæ exhibiting abnormal conditions of the nasal fossæ and maxillary antra.

Mr. CECIL GRAHAM produced a report from Dr. E. H. Kettle on the case of Tuberculous Inferior Turbinate shown at the last meeting, and also exhibited microphotographs with tubercle bacilli present.

Mr. G. SECCOMBE HETT showed a soldier who had been wounded in the face, the bullet having passed through both antra and caused suppuration which was afterwards cured by the Caldwell-Luc operation.

Sir WILLIAM MILLIGAN reported a case of Bone impacted in the Left Bronchus for six months which he removed by upper bronchoscopy with successful results. He also exhibited a microscopic section of a subglottic tumour (lymphangiectasis) invading the upper part of the trachea. It was pointed out that although tracheal growths are very rare, tumours of the subglottic region are much more common. He also showed photographs of a large dentigerous cyst of the lower jaw cured by operation.

Mr. H. L. WHALE showed a female, aged 52, suffering from a large Perithelioma of the Maxillary Antrum, the growth having recurred five months after operation.

Mr. C. W. M. HOPE showed two cases of Esophageal Stricture in children aged 7½ and 18 months respectively. There had been no history of trauma in either case, and he considered that the condition was of the same type as congenital hypertrophic stenosis of the pylorus. Both children had suffered from daily vomiting since birth but were not emaciated. After treatment with bougies the vomiting ceased and soft solids could be swallowed for the first time.

Dr. DAN MCKENZIE exhibited an Oesophagus from a child, aged 2½ years, showing cicatricial stenosis caused by swallowing half a teacupful of a poison for bugs.

Mr. W. STUART-LOW showed a patient (seen at the last meeting) suffering from Epithelioma of the Tonsil, to illustrate the results which he had obtained by puncturing the glands in the neck with the diathermy needle.

Dr. DUNDAS GRANT exhibited a Rabbit's Vertebra which he had removed from the right lower bronchus by superior bronchoscopy.

Mr. W. M. MOLLISON showed a patient upon whom he had operated for Epithelioma of the Larynx, who was now suffering either from recurrence or from granuloma in the anterior commissure.—Sir FELIX SEMON stated that in such cases it should always be the rule to remove a piece for microscopical examination before undertaking a second operation, as in many instances the tissue was found to be non-malignant.

Dr. IRWIN MOORE showed a patient with an Early Nasopharyngeal Growth, probably a vascular fibroma.

Mr. C. A. B. HORSFORD showed a patient with Early Epithelioma of the Vocal Cord causing slight impairment of mobility.

SECTION OF ELECTRO-THERAPEUTICS.

Exhibition of Cases and Specimens.

A CLINICAL meeting was held on March 19th, Dr. IRONSIDE BRUCE, President of the section, being in the chair.

Dr. E. P. CUMBERBATCH showed two patients whose malignant growths (of the tongue and cheek) had been cured by the use of diathermy, though both had been pronounced inoperable by ordinary surgery. The diseased areas now looked quite healthy. In reply to questions, he said he used a current of 1.4 milliamperes, and general anaesthesia was employed. He described his technique.

Dr. C. RUSS showed two exhibits: (1) Bacteria Moving during Electrolysis; and (2) Changes Produced in Bacilli Coli after Electrolysis. There was a control slide from an ordinary case of coli cystitis and another showing the bacteria after several weeks' treatment of such a case, the elongation of the bacilli being plainly evident. There were also changes in the reaction to the Gram stain, showing there was an alteration in the chemistry of the bacterial envelope. Other slides showed the changed form of the colon bacilli due to the continuous passage of a weak current (1/15th of a milliampere) through the tubes containing the bacilli in a fluid closely approximating to that in the bladder. The lack of virulence of the changed bacilli was quite evident.

—Dr. ETTIE SAYER described a case of Streptococcal and Pneumococcal Diarrhoea in which electrical treatment following the use of an autogenous vaccine resulted in a similar elongation of bacilli to that described by Dr. Russ.—Dr. C. H. BROWNING discussed the question, alluding to the similar work of Dr. Ainley Walker at Oxford in the case of typhoid fever. The same attenuated effect could be brought about by means of inhibitory sera.

Mr. LINDSAY LOCKE demonstrated the removal of foreign bodies from the tissues by means of the Ironside Bruce X ray director and described the technique.

Dr. W. J. TURRELL exhibited some simplified electrodes for diathermy and static treatment, and Dr. W. J. S. BYTHELL showed a series of interesting skiagrams of bullet wounds of the skull. Some of the cases showed no cerebral or nervous symptoms, though the bullet was still *in situ* (resting on the tentorium in one case and embedded in the petrous bone in another). In others, where a shattering effect had occurred and there was much brain damage, death had occurred or was imminent.

Dr. ROBERT KNOX showed prints illustrating diagnostic points in a case of new growth of lung and one of malignant disease of the stomach. He also exhibited a remarkably good skiagram of a dermoid cyst containing hair, teeth, and bone.

Dr. ANNESLEY ECCLES showed skiagrams of a girl, aged 3½, who swallowed a foreign body, which was afterwards found to be a pin in the left bronchus, with the point directed upwards. Removal was effected by means of the bronchoscope, which was used with difficulty owing to the small size of the air passages.

Dr. STANLEY MELVILLE showed, by means of a selection of skiagrams, the value of "tidal percussion," as taught by Sir Robert Philip, of Edinburgh, as an early diagnostic sign

of pulmonary tuberculosis. He had found it specially useful in screen examinations. He hoped members of the section would investigate the matter further.

Dr. J. A. CODD showed a useful modification of the tubestand, which enabled a better application to be made to such regions as the axillæ and the root of the neck. He also demonstrated his method of making tracings of the shape of the stomach at various periods in different colours. The drawings were made to overlap and the colour distinction enabled a ready comparison to be made.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Etiology of Diphtheria.

A MEETING of this society was held on March 12th, Mr. HERBERT JONES, the President, being in the chair.

Dr. W. G. WILLOUGHBY read a paper on the Etiology of Diphtheria, in which he dealt with the incidence of the disease among similar classes of people living on different soils. After stating that Löffler's discovery of the specific bacillus of diphtheria enabled him to claim in 1884 that he had satisfied the three postulates of Koch with reference to the relation of a micro-organism to a disease, he maintained the fact remained that though we could not have the disease without the bacillus, yet many individuals harboured the bacillus without suffering from the specific disease, and until we knew what conditions other than the bacillus of diphtheria were necessary for the production of the disease, or what caused the bacillus to become pathogenic, the disease would not be stamped out. He had frequently noticed that the cultures from an infected throat where the patient had no, or very trifling, symptoms were more free from secondary bacteria than the cultures from a severe case, and also that in cultures from cases waiting for discharge from hospital where the patient had been clinically well for some time, but where the bacilli were persistent, cultures were obtainable most free from other organisms and most perfect as specimens of diphtheria morphologically. Referring to the discussion at the Blackpool Congress of the Royal Sanitary Institute last year, when Dr. Hugh Snell gave a careful compilation of figures showing that apparently there was less diphtheria in those districts where institutional treatment was not adopted, he expressed the opinion that the true explanation of these figures was district immunity, and that diphtheria was of such varied incidence according to locality that one district could not be compared with another. Whatever was left undone in a non-diphtheria district there would obviously be less diphtheria than in a district where the disease was endemic. He then gave an interesting comparison of the relative incidence of about 1100 cases which had occurred during the past 20 years on houses of the same class and occupied by persons of about the same social position situated respectively on alluvium, on the beach, and on the chalk. Among the houses on the alluvium 46 per cent. were affected and 56 per cent. of the cases occurred; among those on the beach 24 per cent. of the houses were affected, and 21 per cent. of the cases occurred; while among the houses on the chalk 30 per cent. of the houses were affected and 23 per cent. of the cases occurred.

Dr. J. T. C. Nash expressed the opinion that second attacks with no clinical symptoms might possibly account for epidemics. He had found that there was no difference between the susceptibility of healthy and weakly children.

Dr. J. J. PATERSON said that in the East Berkshire district dampness of sites did not alone account for endemicity of diphtheria. In the past six or seven years most of the cases occurred in low-lying districts on the riverside where ground water was always high and fluctuating, but in another part away from the river where the ground was even more water-logged on account of an impervious crust or "pan" between soil and subsoil there were comparatively few cases, and these of a sporadic nature.

Dr. VEITCH CLARKE considered that the power of resistance of individuals was too often overlooked.

Dr. SIDNEY LAWRENCE advocated keeping a stock of antitoxin for the use of practitioners at fire-stations.

Dr. CHARLES PORTER thought that far too much importance was attached to the taking of swabs from contacts.

Dr. ORR agreed that soil had a material effect on the spread of diphtheria through the dampness lowering vitality.

Mr. T. W. N. BARLOW said that in Wallasey swabbing was not methodically practised in hospital, and return cases were infrequent.

The PRESIDENT was not convinced that the general swabbing of children in an affected school had much effect in reducing the number of cases of the disease.

Dr. H. N. HARDING, Dr. H. J. CATES, and Dr. C. SANDERS also took part in the discussion.

HUNTERIAN SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held at the Royal Hospital for Diseases of the Chest, City-road, E.C., on March 10th. The proceedings were all clinical, and full use was made of the resources of the hospital not only in clinical and pathological material but also for demonstrations, the new out-patient building with museums and lecture-room and well-equipped pathological laboratories, radiology and cardiology rooms being requisitioned.

Dr. A. C. JORDAN gave a fluorescent screen demonstration illustrating the examination of the lungs, heart, aorta, posterior mediastinum, œsophagus, and stomach.

Dr. A. W. STOTT gave a demonstration of the electrocardiograph, showing tracings from cases of heart-block, &c.

Dr. CARNEGIE DICKSON showed in the pathological department recent specimens from a case of Thoracic Aneurysm and a case of Sarcoma of the Left Chest, spreading from the glands at the left root. The wall of the left auricle had been destroyed on one side by the growth, which had in part replaced it. Both these specimens were compared with skiagrams taken during life. Microscopic preparations were shown illustrating cerebro-spinal meningitis, both the meningococcus and the meningococcal leptothrix being demonstrated. Dr. Dickson also demonstrated the technique of the Wassermann reaction.

Dr. JORDAN exhibited a series of war injuries on the epidiascope, and Dr. D. BARTY KING exhibited some illustrations from Professor Ghon's book, of which he has just completed a translation. Dr. King also showed a skiagram to explain a form of recurring local bronchopneumonia in children difficult to distinguish clinically from chronic pulmonary tuberculosis.

Dr. A. T. DAVIES and Dr. R. MURRAY LESLIE showed some interesting heart cases in the wards of the hospital. In two cases of paroxysmal tachycardia exhibited by Dr. Leslie marked benefit had followed specific treatment, instituted in each case after a positive Wassermann reaction had been obtained. Dr. Leslie also showed a man who suffered from two or three attacks of true angina pectoris every day—a disease scarcely ever encountered in hospital practice.—Dr. DAVIES showed two cases of complete Heart-block, the auricles and ventricles beating with independent rhythm. In both cases the rate of auricular and ventricular beat was obtained by counting in the X ray room, by the polygraph, and by the electrocardiograph. The results obtained by these three different methods agreed very closely.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Exhibition of Patients.—The Role of High-Frequency Current in the Treatment of Tumours of the Bladder.

A MEETING of this section was held on Feb. 26th, Dr. F. CONWAY DWYER, the President, being in the chair.

Mr. W. S. HAUGHTON, in showing a case of Double Congenital Dislocation of the Hip treated by the Lorenz Method, said the treatment extended a little over two years, which was about double the normal time required. The delay was due in the first instance to gastric attacks, and then to an attack of measles. Double dislocation cases always took longer to treat, as the stages had to be gone through more gradually. Skiagrams before the treatment and during its progress were exhibited, and attention was directed to the relation of the head of the bone to the acetabulum, the development of the bone, the development of the femur, and the development of the acetabulum.

Mr. W. C. STEVENSON showed a similar case treated by the same method. He said that the left hip was easier to reduce than the right, and it was also found easier to keep in position. The right hip had only recently been taken out of plaster. Massage treatment was now being carried out in order to develop the strength of the leg.

Mr. SETON PRINGLE, in showing a case of Arthroplasty of the Knee for Bony Ankylosis, said he believed it was the first one of the kind done in Dublin, and it had been a hopeless failure. The man, some two years ago, had accidentally stuck a penknife into his knee-joint. The joint became septic, and nine months afterwards he had bony ankylosis, with the leg almost at a right angle. Mr. Pringle had been reading of Murphy's work, and he decided to try arthroplasty. The technique was carefully followed. The essential points of the operation were to remove the old articular surface and remodel the bones, and then to turn in from the tibia and femur flaps to cover the bones. The leg was then put up with an extension of 20 lb. on it for from three to five weeks, after which time the patient was allowed to develop active movement. When the patient was permitted to leave the hospital he had a fair amount of movement in the joint. He wore a splint and used crutches for some time, but about four months after operation he gave the joint a wrench. There was now very little movement in the joint, and it was very painful. X ray photographs of it before and after operation were shown. He believed the operation could be done with a successful result. Murphy had not published a long list of results, but stated that a large number of cases did well, and that others did not do well.—The PRESIDENT remarked that the operation was very new in Dublin, and the evidence furnished in this case was valuable.

Mr. ADAMS A. MCCONNELL read a paper (illustrated by intravesical photographs) on the Role of the High-frequency Current in the Treatment of Tumours of the Bladder. He had treated several cases by this method since he learned the technique from Beer in New York three years ago. After relating the histories of four cases, and illustrating the course of the treatment by intravesical photographs and by radiograms, he came to the following conclusions. The high-frequency current is the method of choice for the treatment of vesical papillomata which are small in size, apparently benign in nature, and in patients who are not good subjects for an anæsthetic; it relieves the symptoms and checks hæmorrhage from inoperable carcinomata of the bladder. It may be used with advantage as a preliminary to operation in patients anæmic from much bleeding. After operation it should be used to remove recurrent growths as soon as they can be seen with the cystoscope. He advocated the removal of villous tumours by operation and routine cystoscopic examination at intervals of a month for some years afterwards. It was irrational to wait for symptoms before making a diagnosis of recurrent growths, for papillomata may remain in the bladder for long periods without producing hæmorrhage. Mr. McConnell demonstrated the working of the apparatus.—The PRESIDENT said he believed this to be the first communication on the treatment of the bladder by this method. The surgical treatment of these cases was not satisfactory. He thought Mr. McConnell had brought out very clearly the great value of this treatment and its limitations not only for the treatment of tumours, but for their after-treatment.—Mr. PRINGLE had treated one patient by this method whose tumour occupied practically two fields of the cystoscope, and it was now over a year since the treatment, and there was as yet no recurrence. The treatment did not disturb the patient and did not cause pain. He would advocate its use in all cases of clinical epithelioma as a curative measure, not as a pre-operative method.—Mr. C. A. BALL, with regard to the question of recurrence of vesical tumours after operation, mentioned a valuable suggestion—i.e., washing out of the bladder with an antiseptic strong enough to kill any cells that may be left after the removal of the tumour. This, he thought, might diminish the possibility of recurrence. He considered that a tumour might be present for a long time before it produced bleeding.—Dr. W. M. CROFTON asked if radium tubes had been used for treating vesical tumours, as it struck him that they might be malignant.—Mr. A. J. MCA. BLAYNEY said that the ease of the transperitoneal operation depended upon the constitutional habit of the patient. It was easy in thin subjects but difficult in fat ones. The high-frequency method should be recognised as the one for dealing with papillomatous tumours.—Mr. MCCONNELL replied.

Reviews and Notices of Books.

Essentials of Human Physiology.

By D. NOËL PATON, M.D., B.Sc. Edin., F.R.C.P. Edin., F.R.S., Professor of Physiology, University of Glasgow. Fourth edition, revised and enlarged. London and Edinburgh: W. Green and Sons, Limited. 1914. Pp. 557. Price 12s. net.

ABOUT seven years have elapsed since the third edition of this work was issued. The number of pages has been increased from 477 to 557 and the figures from 181 to 213, some of these having with advantage been redrawn; some of the sections have been rewritten, others rearranged; and greater prominence has been given to those parts of physiology which bear more directly upon medical and surgical practice, while there are references to the disturbances of function which occur in morbid conditions. The importance of practical work is rightly emphasised, and in the text references to this matter are constantly met with. We take it that other publications by the author deal with this aspect of the subject.

This edition is practically on the same lines as the previous ones, and the schematic diagrams are more or less those that most teachers of physiology sketch on the blackboard during lecture. Many are simple and effective, and the author has done well to increase their number. Too elaborate diagrams obscure what simple diagrams make clear. In the reference to calcium salts and blood coagulation it might be well to state that the oxalates to be added are soluble oxalates. Reference to the fungiform papillæ of the tongue seems to be omitted. The statement that the parotid "opens on the side of the cheek" seems rather vague, and so is the following: "On each side between the mouth and the pharynx is the tonsil." The formula of cholesterol—in this edition cholesterol—is given as $C_{26}H_{48}OH$. Other observers give $C_{25}H_{47}OH$. In connexion with the reference to jaundice it might be well to state that there are other causes besides the one mentioned. In the summary of the functions of the liver nothing is said about its relation to blood clotting. We are glad to see that dietetics and foodstuffs generally and their metabolisms are dealt with in a lucid and practical manner. A much fuller account is now given of the nervous and chemical regulators of metabolism commensurate with the advances in this very practical field of study. Just a little over 20 pages are given to excretion by the kidneys, and the urinary tests are practically omitted, as the tests for the various constituents of the urine must be studied practically.

This edition is a decided improvement on its precursors, and gives a fair, all-round, lucid, and attractive exposition of the so-called "essentials" of physiology in a manner which will appeal to students.

Dreams.

By HENRI BERGSON. Translated, with an introduction, by EDWIN E. SLOSSON. London: Fisher Unwin. 1914. Pp. 62. Price 2s. 6d. net.

THIS is a translation of a lecture on the theory of dreams which Professor Bergson delivered before the Institut Psychologique on March 26th, 1901—i.e., some 14 years ago. It has not, apparently, been altered by him in any way, though in a footnote on page 39 he refers (1913) to Professor Freud's work and to the development of methods of psycho-analysis in recent years.

Professor Bergson shows first that external stimuli of various sorts, visual, auditory, tactile, &c., impressions which pass unperceived in the waking state, reach the mind and form the materials of our dreams, but do not suffice to produce these dreams, mainly because they are vague and indeterminate. He asks, "What is the form that will imprint its decision upon the indecision of this material?" and answers, "Our memory." Memories weave the web of our dreams, old forgotten memories, fragmentary it may be, memories of objects perceived unconsciously during the distractions of waking life. In this latter state memories are as it were organised, closely connected with the situation, occupation, or action of the moment. A thousand other memories are crowded out, but let the individual become disinterested in his situation or action, let him sleep, in other words, and these memories "arise from the depths: they rise, they move, they perform in the night of unconsciousness a great *danse macabre*. They rush together to the door which has been left ajar." Not all, of course, emerge from unconsciousness, but those emerge which can assimilate themselves with the external and internal sensations that are then reaching our sleeping mind, and when this union is effected between the memory and the sensation we have a dream.

Professor Bergson believes that all our memories, good and evil, pleasant and unpleasant, are thus stored away, and his conception is a wider and more philosophical one than that of Professor Freud, for whom the dream is symbolic of desires or fears which we refuse ordinarily to admit to consciousness, inasmuch as they are either painful or morally repugnant. In his preface the translator briefly indicates the divergence between the two theories in this respect.

Considerations of space make it impracticable to enter on a detailed criticism of Professor Bergson's little book. We feel that he is unnecessarily landing himself in difficulties when he asserts that the creative dream, so-called, is not really a dream, or that that part of ourselves which then labours is not the same as that which sleeps. It may be questioned, further, whether in waking life our memories of the moment inevitably derive from what we are then thinking or doing; but much of the meaning of the author's distinction between waking and dream processes depends on the assumption that this is so. The volume is characterised by that lucidity of thought and expression and grace of style that we have come to associate with the work of its distinguished author.

Recreations of a Physician.

By A. STUART M. CHISHOLM. London and New York: G. P. Putnam's Sons. 1914. Pp. 328. Price 7s. 6d. net.

Dr. Stuart Chisholm, an American medical man, gives us in his "Recreations of a Physician" a delightful series of ten essays on subjects so varied as Specialisation, Physicians as Men of Letters, Banquo, the Symbolism of Names, Royal Authors, the Inherent Spirit of Medicine, Translations of Horace, Some Features of the Science of Medicine in the Seventeenth Century, the Picard in Fiction, and the Prevention of Disease. In the essay on Horace the author's graceful translations of *Jam Satis Terris* (I. 2) and *Quis desiderio* (I. 24) are worthy of notice. They illustrate, however, in places the extreme difficulty of accommodating the rhythm of a tongue that knows not quantity (in the classical sense) to the requirements of metres that depend entirely on quantity for their swing. For

example, the dactyl in the lesser Sapphic Ode hardly comes trippingly from the tongue in such an English line as—

Which in | Persian | warfare would | better | glisten

Unless, indeed, it were hideously slurred—

Which in | Persian | warfer 'ud | better | glisten.

The corresponding double choriambus of the third Asclepiadean Ode, however, reads better—

Who shall | measure our tears | who be ashamed | to grieve.

We note a curious error on p. 21, where St. Andrews University, Edinburgh, is mentioned. We suppose the error arose from the association of St. Andrews with Edinburgh in Parliamentary representation.

There are points in the article on Specialisation to which exception must be taken. It is surely hardly correct to say, as the author does (p. 5), that while scissors and forceps were discovered in excavations at Pompeii, "the only knife known to the early anatomists was the razor. The invention of the scalpel was due to either Fabricius or Cæsalpinus, both teachers of anatomy in Padua in the latter part of the sixteenth century." In his "Surgical Instruments in Greek and Roman Times" Dr. J. S. Milne devotes an entire chapter to the knives used by Greek and Roman surgeons, the various forms of which, including scalpels, bistouries, fleams, and lancets, are profusely illustrated. Many specimens are to be seen in the British and other European museums. In the Wellcome Museum of History of Medicine, for instance, are two undoubted bronze Græco-Roman scalpels. Plate IV. in Dr. Milne's book shows also an ex-voto tablet now in the museum at Athens which was found on the site of the Temple of Æsculapius on the Acropolis. On this tablet is carved an open surgical dressing-case that looks remarkably modern, and contains besides curved and straight bistouries an instrument apparently having a tenaculum at one end and an aneurysm needle at the other. A much more serious matter is the author's revamping (p. 5) of the old, widely disseminated, but now discredited story that Pope Boniface VIII. in his Bull *De Sepulturis* issued a decree against dissection to which is attributed the supposed antagonism of the ecclesiastical authorities to practical anatomical study. The Bull itself completely negatives the idea that it had any reference to anatomical study, and the subsequent history of events shows that it had no influence thereon. It is remarkable how erroneous ideas, originated sometimes out of pure malignity, sometimes out of ignorance more or less culpable, will persist and be reiterated, presumably in good faith, long after their foundations have been completely demolished. Dr. Chisholm also repeats the story of the persecution of Vesalius by the Inquisition, which it has been alleged led to his ill-fated pilgrimage to the Holy Land. In a monograph by Dr. G. Matheson Cullen, recently reviewed, both these particulars in the life of Vesalius will be found fully dealt with.

La Stase Intestinale Chronique.

Par le Docteur E. SORREL, Ancien Interne, Lauréat des Hôpitaux de Paris et de l'Hôpital Maritime de Berck-sur-Mer. Paris: G. Steinheil. 1914. Pp. 252.

In this country there has been much discussion on the views which were first brought forward by Sir Arbuthnot Lane on the importance of chronic intestinal stasis and the appropriate treatment for this condition; in other countries

many have definitely adopted the view that this condition is productive of serious conditions. In the British Isles the opinion appears to be steadily gaining ground that the importance of the condition has been but little overrated, and that operative treatment offers in most cases the best procedure. In France very little has been written on this subject, and the book before us is the first in that country to be devoted entirely to chronic intestinal stasis. The author accepts practically in their entirety the views which have been so ably advocated by Sir Arbuthnot Lane; he discusses the anatomy of the parts concerned, the etiology of the stasis, the symptoms and the treatment; and he concludes his treatise with a large number of cases of the condition, for the most part culled from medical literature, but also containing several cases which have been under his own care. His conclusion as to the treatment may be summarised as follows: If adhesions which interfere with the onward passage of the intestinal contents are few in number they may be divided, but in all other cases one form or another of intestinal anastomosis will be required. A useful bibliography is appended.

The book is an earnest study of the subject.

LIBRARY TABLE.

Transactions of the National Association for the Study of Pellagra. Report of the Second Triennial Meeting. With illustrations. Columbia: The R. L. Bryan Company. 1914. Pp. 409.—The second triennial meeting of the American National Association for the Study of Pellagra was held at Columbia, South Carolina, in October, 1912. The time that has elapsed since the papers were read and their publication in this report in 1914 has robbed some of them of the interest and freshness that they possessed two years ago. Nevertheless, the contributions now printed are, on the whole, of value, and some of them add to our knowledge of the subject. Dr. Rupert Blue, late Surgeon-General of the United States Public Health Service, gave an address on the problem of pellagra in the United States, and Dr. J. W. Babcock, President of the association, contributed a paper in which he discussed the question of how long pellagra has existed in that country, and expressed the opinion that it must have been present in some of the States as far back as 1828. Dr. C. H. Lavinder, of the United States Public Health Service, who is a well-known expert on pellagra, and who has conducted official investigations concerning the disease, supplied a paper on its prevalence and geographical distribution in the United States, and in this he mentioned that within the last six years (up to 1912) at least 30,000 cases had come under observation. Dr. R. M. Grimm, a member of the same Government service, wrote on some facts in the epidemiology of the disease. Among other contributors were two well-known London authorities on the subject—namely, Dr. F. M. Sandwith and Dr. L. W. Sambon. The former discussed the question, Can pellagra be due to a deficiency of nutrition? and the latter, being unable to attend the meeting, sent a paper on some special points of epidemiological interest in pellagra. Several distinguished experts from the continent of Europe also read or sent contributions, and among them may be mentioned Dr. B. Gosio (Rome), Dr. G. Antonini (Milan), Professor V. Babes (Bucharest), Dr. Jean Nicolaidi (Paris), and Dr. Umberto Grillo (Udine, Italy). Some of the

remaining contributors dealt specially with the local history of the disease, its diagnosis and treatment. The volume furnishes a good deal of interesting information on the various aspects of the disease.

The Voyages of Captain Scott. By CHARLES TURLEY. With an introduction by Sir J. M. BARRIE, Bart. London: Smith, Elder, and Co. 1914. Pp. 440. Price 6s. net.—This excellent little volume is a compressed edition of "The Voyage of the *Discovery*" and "Scott's Last Expedition," prefaced by a charming introduction by Sir J. M. Barrie, which gives an account of Scott's boyhood. It is just the book to give a boy, especially at this time, when, to use Lord Beaconsfield's fine phrase, "The youth of a nation are the trustees of posterity." For this is a story of endurance under inconceivable hardships, of a long-sought-for goal at last arrived at, of cheeriness, good fellowship, and every quality necessary to make a nation strong. In Scott's own words, "The combination of individual effort for the common good has achieved our results, and the absence of any spirit of self seeking." There are few accounts of travel more pathetic than Scott's simple notes of the homeward marches on the last journey. Here is the last day's note: Two of the expedition were dead, Evans, who died in his comrade's arms, and Oates, who dragged his weary body out into the blizzard so that he might not be a further burden. Evans died on Feb. 17th, Oates on March 16th, and on March 29th Scott wrote (they had been confined to their tent with a blizzard blowing ever since March 19th): "I do not think we can hope for any better things now. We shall stick it out to the end, but we are getting weaker, of course, and the end cannot be far. It seems a pity, but I do not think I can write more." And that was the end. When the search party arrived in the following summer they found in the tent besides the diary sundry letters, among which were two, one to the wife of Dr. Wilson and one to the mother of Lieutenant Bowers, which in the midst of the long-drawn agony Scott had managed to write.

The Prescriber's Formulary and Index of Pharmacy. By THOMAS PUGH BEDDOES, M.B., B.C. Cantab., F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1914. Pp. 132. Price 2s. 6d. net.—The second edition of this handy little pocket book, now before us, has been adapted to the new Pharmacopœia. The apothecaries' measure is, however, retained, with such variations from the former edition as are necessary to make them conform to the metric doses in the Pharmacopœia. The internal and regional remedies are now preceded by a synopsis of the alterations in the Pharmacopœia, and followed by a classified list of drugs arranged under their therapeutic properties and a section on the treatment of poisoning.

JOURNALS.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLIX. No. 3. Feb. 25th, 1915. Cambridge University Press. Pp. 113-146. Price 2s. 6d.—The Influence of Temperature on the Secretion of Sweat, by J. M. O'Connor. The experiments were made on the foot of cats anaesthetised with 1-2 grammes ethylurethane per kilo, given by the mouth. The foot was enclosed in a special apparatus through which dry air—about 1½ litres per minute—was sucked. The amount of water was determined by absorption in sulphuric acid. To determine if the loss of water was an active or a passive process the effect of atropine injections was observed, as well as section of the sciatic nerve. The loss of water in the normal anaesthetised cat

seems to be passive, and there does not appear, under the conditions adopted, to be an active secretion of sweat, except under special conditions of temperature. The author concludes that (1) the normal loss of water from the foot of the cat is a passive process; (2) active sweating appears in the cooled anaesthetised animal (a) when the body temperature is raised to about normal, or (b) when the subcutaneous temperature reaches about 43°C. The result points to the conclusion that the former is a protection against a rise of temperature of metabolic origin, and the latter a reflex protection against a local rise in skin temperature.—Observations on Anaesthesia by Phenyl-ethyl Malolyl Urea, by W. L. Symes. This substance is advertised as a powerful hypnotic under the name of luminal. Its sodium salt, which is freely soluble in physiological saline, yields an unstable solution. This drug, dissolved as required, was used to obtain uniform anaesthesia for prolonged periods and without marked diuresis. Animals have been kept unconscious for various periods up to 18 days. Most of the experiments were made on cats and a few on rabbits, the latter being somewhat less susceptible. The results may be summarised as follows: With cats, for experiments lasting 3-5 hours, a subcutaneous dose of 0.2 gm. luminal per kilo is usually sufficient and safe. Except with old cats, anaesthesia is complete within one hour. Since the maximum effect only is produced, 0.15 gm. per kilo may be given subcutaneously or by the mouth in the evening, and if necessary an additional 0.5 gm. per kilo on the following morning 10-20 minutes before commencing the experiment. Cats under luminal are markedly poikilothermic. Unless they are warmed their rectal temperature may fall below 30°C; if they are overwarmed it may reach 43°C. without warning from change in respiration. Cats may, with care, be kept unconscious for days and recover completely. Rabbits are conveniently and rapidly anaesthetised by intravenous injection of a 10 per cent. solution.—Contributions to Physiological Climatology (Part II.), by W. A. Osborne. This is a continuation of a research published in 1910 in the *Journal of Physiology*, in which it was shown that the skin is a moist surface and evaporation from it will be determined in large measure by the physical state of the air, its temperature, humidity, and movements. The present research was carried out in the summer (Australian) of 1912-13 by the methods already used by the author, with the addition of anemometric readings. It was found that despite varying humidity and velocity it is the temperature of the air, under the climatic condition of the experiments, which is the leading factor in skin evaporation.—On the Alleged Influence of Adrenalin and of the Sympathetic Nervous System on the Tonus of Skeletal Muscle, by Yas Kuno. After referring to the two kinds of nerve ends in voluntary muscle, one in connexion with medullated and the other with non-medullated—probably sympathetic—nerve-fibres and their probable physiological significance, the author describes the nature of his experiments, which were made on the excised sartorius of *Rana esculenta*. The sartorius was placed in a Keith Lucas muscle trough, by means of which the muscle can be excited and its contraction registered while immersed first in about 50 c.c. of Göthlin's modification of Ringer's fluid. After a certain time the trough was emptied and refilled with a similar fluid containing varying doses of adrenalin. The author finds that adrenalin up to the strength of 6:100,000 has no appreciable influence on the curve of contraction of the sartorius of the frog. The tonus of the hinder extremities is not altered either by the injection of adrenalin or by division of the rami communicantes, whereas the loss of tonus in frogs after division of the anterior roots of the spinal nerves is always marked by a relaxation of the muscles of the affected side. Muscles which are still in connexion with the spinal cord show on loading a gradual increase in length which may last 30 or 40 minutes. This phenomenon is best marked in "cold frogs." Section of the rami communicantes does not alter the rate at which this takes place, but the phenomenon is practically abolished by previous division of the anterior roots. The muscles of a "cold frog" which are still in connexion with the spinal cord show a marked contraction remainder after each twitch due to indirect excitation. The contraction remainder gradually disappears. Section of the rami communicantes does not alter this phenomenon, but section of the anterior roots almost abolishes it.

THE LANCET.

LONDON: SATURDAY, MARCH 27, 1915.

Shell Explosions and the Special Senses.

OF the many interesting and important types of case which are beginning to emerge from the welter of warfare, as conducted by modern methods to the accompaniment of terrific shell explosions, one is specially deserving of study—namely, the type in which there is traumatic diminution or abolition of function of one or other of the special senses. Data concerning the effect of shell explosions upon taste and smell have not yet been forthcoming in sufficient detail for any conclusions to be drawn; and in any case we should not expect it to be as immediate in its manifestations as the effect upon sight or hearing, and reference will therefore be made mainly to cases of traumatic amblyopia or amaurosis and traumatic deafness. Clinically and pathologically, several groups may be distinguished. There are, firstly cases where the phenomena seem to be the result of inhibition of function, such as is observed when stimulation is intense and prolonged. It is well known, as Dr. JAMES NIVEN reminded his audience in a recent address on the Effect of Noise on Health, delivered before the Manchester Statistical Society, that boilermakers, riveters, blacksmiths, and people working on railways, after a time become deaf to certain sounds as a result of prolonged monotonous noise, especially if it is interrupted rather than continuous. Those terminals of the auditory nerve apparatus which respond to notes of a certain pitch are over-stimulated and their function inhibited, just as workers in snuff mills soon cease altogether to respond to the recurring stimulus of irritating particles on the nasal mucosa. It is quite possible that much more concentrated and rapid stimulation may produce the same effect. Blinding of the retina by direct sunlight is responsible for a series of cases after every big solar eclipse, where the observer has failed to protect his eye sufficiently. It is, then, a general experience, whatever be the sense avenue involved, that from over-stimulation the nerve elements concerned become fatigued and then paralysed. The question at once arises whether there is any actual organic change in such nerves and nerve mechanisms, entailing more or less permanent defect of function, or whether, in the absence of structural damage, this "fatigue paralysis" will disappear. In any given case it may be difficult to decide, but there is little doubt that, both for the eye and ear, severe and concentrated over-stimulation may lead to permanent mischief.

Not always to be distinguished from this group is a second class of case where the disturbance of function is supposed to result from a "commotio," a sudden jar to nerve elements, a "shock," throwing mechanisms out of gear either peripherally or centrally. As there is difference of opinion as to the presence or absence of a genuine organic change (however slight) in cases of "railway spine," of traumatic neurasthenia of spinal type, so is it probable that there will be division of opinion as to the pathology of "commotio" of the special senses. It may be part of a general commotio cereбрalis, or it may be local and peripheral, e.g., a labyrinthine commotio. A number of cases, both civil and military, have been recorded at one time or another where the impact of a projectile has reduced a segment or more of the spinal cord to pulp, though the dura is found to be intact and the bullet has not directly touched either dura or cord. Cases have also been recorded where a heavy fragment of a shell, striking the neck, has produced death by sudden and violent dispersion of the cerebro-spinal fluid within the tough dura, structurally damaging and paralysing the adjacent medullary centres. A sudden and powerful commotio in such cases can effect the most striking organic change. Now it is at least conceivable, and in the opinion of some it is possible, that a sudden jar to nerve elements produced by the violent explosion of a shell in the closest proximity to eye or ear may effect an organic change, very much less in degree, no doubt, but still of the same nature as that above described. A third class of case is clearly of the nature of traumatic hysteria. In regard to this group also, however, it may be questioned whether there may not be some organic basis on which the neurosis is implanted, whether the "shock" does not effect a change the functional expression of which is identical with or comparable to the functional disturbance that we know as hysteria.¹

As illustrating the suggestive way in which this subject may be worked out, reference may be made to a meeting of the Académie de Médecine of Paris on Jan. 19th, when M. LANNOIS and M. CHAVANNE communicated an important paper on total deafness due to the sonorous vibrations produced by shell explosions, of which they had observed 50 cases since the beginning of the war. They attributed the deafness to different conditions. In some cases they considered that it was the result of a kind of inhibition, such as is observed when the olfactory or optic nerve has been submitted to too intense or too prolonged stimulation. The deafness due to this "fatigue paralysis" disappeared in some days. In other cases the ear is not at fault and the deafness is a symptom of cerebral concussion. In still other cases there are hystero-traumatic phenomena, which may take the form of deafness, deaf-mutism, or deaf-mutism and blindness. Such manifestations are relatively rare. They were observed especially in soldiers who had been more or less buried in the

¹The Study of Shell Shock, by Captain C. S. Myers, R.A.M.C., F.R.S., THE LANCET, Feb. 13th, 1915, p. 316.

earth thrown up by the bomb. These different forms were found both isolated and combined into complex types. They also were sometimes accompanied by labyrinthine concussion. The pathology of labyrinthine concussion is ill-defined; there may be simply a labyrinthine commotio, or there may be visible lesions such as hæmorrhage. Labyrinthine concussion may present itself under different clinical aspects. It may coexist with fracture of the skull, the symptoms of which are added to those of the concussion. The fracture may pass through the mastoid and may be accompanied by a lesion of the labyrinth. Labyrinthine concussion may also be accompanied by a rupture of the tympanic membrane. The concussion is frequently attended by loss of consciousness, which is followed by the triad vertigo, tinnitus, and deafness. Nausea and vomiting are rare. All forms of vertigo occur. There may be vertigo in bed, the patient feeling that he is revolving on a horizontal or vertical axis, or there may be loss of equilibrium when standing or walking. The vertigo usually disappears quickly, but the tinnitus is more persistent. The deafness, which is often total at first, frequently remains considerable, the patient hearing only when shouted at. It may be unilateral or bilateral. Bone conduction is diminished and the superior limit of audibility of high notes is lowered. This is the most characteristic sign, and considerable lowering is of bad prognostic significance. The observations of M. LANNOIS and M. CHAVANNE are of great practical interest at this moment.

Housing in Agricultural Districts.

THERE are few problems more difficult, and in some ways few more discouraging, than that of the amelioration of the conditions of working-class housing in agricultural areas in many parts of England. People are apt to regard these areas as identical with "rural districts," and to judge the position from facts and figures relating to the latter. Unfortunately, however, most of the rural districts which show housing progress, in the form of increase in new cottages and of demolition or substantial repair of those which have become unfit for human habitation, are districts in the neighbourhood of large towns or of mining or industrial centres, where the housing improvements have been for the benefit of everyone but the agricultural labourer. Exceptions can, of course, be found on large estates, especially where the owner does not depend mainly on farming for his income; something has been done here and there in connexion with small holdings, and occasionally a rural district council has been induced to provide a few cottages. But for the farm hand or shepherd the total change is small, and in many parts, particularly in the south and west, dwellings of bad original construction are now worn out and past any satisfactory improvement at reasonable cost, while no new building is to be expected either from private enterprise or from local authorities. Damp, dark, overcrowded and ill-ventilated

cottages contribute to tuberculosis, rheumatism, and other conditions which naturally make a direct appeal to the sanitarian. A still more serious result, however, in districts where such houses are the only dwellings available to the agricultural population is their undoubted effect in emptying the country of its more efficient stock, a process which has been actively going on for many years, and does not seem likely to diminish.

A recent book on "Rural Housing," by Dr. W. G. SAVAGE, medical officer of health for the county of Somerset,¹ deserves attention in connexion with these questions. Dr. SAVAGE discusses the causes of the failure of the various Housing Acts, including that of 1909, which in some directions was a considerable advance on its predecessors, to meet the housing requirements of agricultural areas through the action of the local authorities. One of the most important of these causes seems to be the want of central driving power. Many county or district councils would not hesitate to carry out duties laid on them by Parliament if they were subjected to a really effective pressure from the central authority. If neglect entailed their supersession or a prosecution, they would have a conclusive answer to local objectors. The Local Government Board, however, is usually unable or unwilling to go beyond remonstrances, and is probably hampered by its functions as a legal court of appeal in cases of dispute between the local authorities and the property owners. Possibly, as Dr. SAVAGE contends, too much of the direct administration has been put on the rural councils, and too little on the county councils. It is now also generally admitted that under any system dependent on local government the local authorities must receive substantial Government subsidies if they are to build country cottages on a considerable scale. The housing grant proposed by the Government early last year has, however, been dropped as a result of the war, and it is questionable whether the proposals then made took sufficient account of the special requirements of the agricultural districts.

Dr. SAVAGE'S book, besides giving a valuable study of such questions as we have referred to, contains much useful practical advice as to the conditions which justify houses being represented as unfit for human habitation, and the steps which can be taken to bring unsatisfactory houses up to tolerable standards of healthiness. In these matters, as well as in respect of the construction of new labourers' cottages, it will be of special service to medical officers of health, on whom at present rests the burden of making the best use possible of the existing administrative position. At the end of the war probably many men who return will have acquired a distaste for town life and would prefer agricultural work in England to emigration if it could be undertaken under tolerable conditions of comfort, of which a reasonably contrived cottage with a little land is perhaps the chief.

Annotations.

"Ne quid nimis."

THE PRESCRIBING OF NARCOTIC DRUGS.

DURING the last year or two legislative measures designed to restrict the use of narcotic drugs to legitimate purposes have been enacted in many countries, but none of them is so stringent or likely to be so effective as an Act which came into force in the United States of America on March 1st, 1915. This Act, which is known as the Harrison Law, is the most important measure of legislation affecting the sale of poisons that has ever been enacted in America, and there is nothing in English law which is comparable with its provisions. The recent growth of the drug habit in the United States has been admitted by the authorities to have been appalling, and the consumption of opium, morphine, and cocaine over and above that required for medicinal purposes has been shown by official figures to be enormous. The evil, in fact, was sufficiently acute to justify a remedy even more drastic than that which has now been prescribed by law. The purpose of this legislation is to keep under strict control all transactions in certain narcotic substances, and in order to effect this object "every person who produces, imports, manufactures, compounds, deals in, dispenses, sells, distributes, or gives away opium or coca leaves or any compound, manufacture, salt, derivation or preparation thereof" is required to comply with specified conditions. The chief part in this campaign against self-drugging will be played by medical practitioners and pharmacists. All members of both callings must forthwith become registered by the Inland Revenue collectors of their districts and must pay a registration fee of \$1 a year. Every medical practitioner in writing a prescription for any of the prescribed drugs is required to write thereon the name and address of the patient and his own address and registration number, and to sign the prescription with his full name. This should occasion little inconvenience, for it will be quite a simple matter to have the registration number printed on prescription forms, together with the name and address. The prescriptions cannot be dispensed more than once, so that the new law definitely disposes of the problem of the repetition of prescriptions for narcotic drugs. A medical practitioner who dispenses his own medicines or requires any of the drugs in question for his own use will be obliged to write his order on an official form supplied by the Inland Revenue and costing $\frac{1}{2}$ d. each. He must make a record, to be preserved for two years, of all such drugs dispensed by him, which record must include the quantity of the drugs dispensed, the date, and the name and address of the patient. There is, however, a provision excusing practitioners from keeping any record of narcotic drugs which they personally administer to their patients. Apparently the new law does not affect the practice of medical men to any greater extent than has just been explained and, judging from the opinions expressed in representative medical journals in America, there is no noteworthy tendency on the part of the profession to object to fulfil the conditions laid down. The new law prohibits a pharmacist from selling to the public any of the drugs affected except on

the original prescription of a duly qualified practitioner who has been registered by the local Inland Revenue officer, and every prescription must be preserved for two years. Further, no pharmacist may be supplied by his wholesale house with any of the drugs unless they are ordered on an official form; the order must be written in duplicate, the duplicate to be retained for two years, and to be available for inspection by the Federal and municipal authorities. The provisions of the Act do not apply to preparations of opium and coca leaves "which do not contain more than two grains of opium or more than one-fourth of a grain of morphine, or more than one-eighth of a grain of heroin, or more than one grain of codeine, or any salt or derivative of any of them in one fluid ounce, or, if a solid or semi-solid preparation, in one avoirdupois ounce; or to liniments, ointments, or other preparations which are prepared for external use only, except liniments, ointments, and other preparations which contain cocaine or any of its salts or alpha or beta eucaine or any of their salts or any synthetic substitutes for them." Since most of the official and commonly prescribed preparations contain a larger proportion of the drugs named than is laid down in the exempting provision the exclusion of weak preparations is not a very serious matter. The American experiment will be watched with interest by other countries, and when the world is at peace again it may well be that other countries will follow the American example.

ELECTROCARDIOGRAPHIC STUDY OF THE ANAPHYLACTIC RABBIT.

THE use of the string galvanometer has shed much light on the physiological and pathological action of the heart not only in animals but in man. It has become an almost necessary part of the equipment of every large hospital. So far the cardiac disturbances in serum anaphylaxis have not received much attention. It is known from the researches of Gay and Southard in 1907 that the heart of the anaphylactic guinea-pig often shows hæmorrhages. Later, by inspection and the graphic method, J. Auer, J. Lewis, and others observed definite pathological alterations of the heart's activity during serum anaphylaxis, such as abrupt diminution in rate in the dying heart. The block was thought to be due to asphyxia. Heart block and other cardiac disturbances have been demonstrated in the dog by the electrocardiograph. It would therefore appear that heart disturbances in serum anaphylaxis of the intact animal are common in this state, and apparently form an integral part of anaphylaxis. John Auer and G. Canby Robinson¹ have studied by the electrocardiograph the main changes which the heart of the anaphylactic rabbit reveals to this instrument. The rabbits were sensitised by repeated subcutaneous injections with horse serum. About four weeks after the last injection the animals were given the final toxic dose of about 9 c.c. into a marginal ear vein. The electrocardiograms were taken at short intervals before, during, and after the injection; the Edelmann string galvanometer was used, the right fore and left hind leg being connected with the instrument. Care was taken to separate the cardiac disturbances resulting primarily from the anaphylactic reaction from those which occurred as phenomena of the

¹ Studies from the Rockefeller Institute for Medical Research, xix., 1914.

dying heart, cessation of respiration being taken as the index of death. Intravenous injection of horse serum into non-sensitised normal rabbits showed no such changes in the electrocardiograms as were seen in the sensitised animals. In the latter marked and various changes of the heart's activity were recorded in 22 out of 24 animals. Changes occurred in fatal as well as in non-fatal cases, after the vagi were cut, as well as when they were intact. As cardiac disturbances are thus a practically constant result of serum anaphylaxis in the rabbit, it is possible that anaphylaxis plays a rôle in the causation of certain cardiac derangements in man.

RINGWORM IN THE TROPICS.

At one time it was believed that the ringworm met with in the tropics was the same as that which is encountered in temperate climes. This view, however, does not now meet with acceptance among experts. Lately some further evidence on the subject has been put forward in a recent number of the *Journal of Tropical Medicine and Hygiene* by Dr. Albert J. Chalmers, director of the Wellcome Research Laboratories, Khartoum, and Mr. A. Marshall, the senior bacteriologist. These experts summarise the history of ringworm in the tropics, and point out that at least seven different species of fungi have already been recognised as the causal agents of the disease. They have now found among schoolboys and youths in the Anglo-Egyptian Soudan a new, and as yet undescribed, variety of tinea which they were able to cultivate in various media. This fungus, it appears, belongs to the class of Fungaceæ of Linnæus, called ascomycetes by de Bary; it also belongs to the family Gymnosaceæ and to the genus *Trichophyton*. The authors propose to give it the name of *Trichophyton curri*. The alopecial patches caused by this fungus are small as a rule, and not very noticeable; the prognosis as regards baldness is apparently good, to judge at least by the cases already observed. A number of different remedies were tried in the treatment of this Soudanese form of ringworm, most of which, however, gave only temporary relief; the best results were obtained by the use of a special kind of tobacco-soap (nicotiana-seife) made in Bremen. With regard to prophylaxis it is thought that much may be done by regular and systematic medical inspection of all children in schools with a view to the discovery of parasitic diseases, and by prompt treatment as soon as evidence of ringworm is found. As the disease seems to spread but slowly in a school much may be done by medical inspection and early treatment to arrest the progress of the infection.

PUBLIC HEALTH IN BOMBAY.

For the first time in its history the city of Bombay—the third city in point of population in the British Empire—has had a death-rate lower than its birth-rate. For the week ending Nov. 21st, 1914, the death-rate was 20·49 per 1000, while the birth-rate was 23·25. The quinquennial averages for this week (1909–1913) were, for deaths 30·91 and for births 24·65 per 1000. On account of the war there had been a large exodus from the city; and if, as an allowance for this, the actual population be estimated at 900,000, the respective death-rate and birth-rate work out as 22·30 and 25·30; even so, the death-rate is lower and the birth-rate higher than the quinquennial average. There is no doubt

as to the fact of the exodus on account of the war, but the birth-rate should have been affected as well as the death-rate by this occurrence; on the other hand, there was a considerable influx into Bombay, from all parts of India, of troops and followers, and of pilgrims. No case of infectious disease occurred among the troops during their stay in Bombay, and the sickness and mortality rates were very low, only seven deaths occurring among soldiers of all classes, British and Indian. All infectious diseases were at a minimum; during 14 days only one case of plague occurred, and this was imported. It may be said with reason that the sanitary condition of Bombay has reached a standard of excellence that reflects the greatest credit on those responsible for the health of the city, and gives them every encouragement to persevere in their efforts to maintain it at its high level.

A NEW TYPE OF FRACTURE OF THE ANKLE.

An important paper on a new type of fracture of the ankle has been published in the *Journal of the American Medical Association* by Dr. F. J. Cotton. It was read at the last annual meeting of the Association. There is backwards dislocation of the ankle with splitting away of a wedge, large or small, from the posterior surface of the tibia. The wedge is displaced backwards and carries the posterior tibio-astragaloid ligaments upwards and backwards with the foot. Fracture of the malleoli is associated with the luxation, and hence the condition is often confounded with Pott's fracture. As a rule, the posterior tibial fragment is separate from the malleolar fragments, though sometimes the internal malleolus and posterior tibial edge are included in one piece that is split away in a spiral line. It has long been recognised that certain cases of Pott's fracture are complicated by backward luxation of the foot. Dr. Cotton claims that nearly all these cases are not examples of Pott's fracture but of the condition now described. His attention was first called to it by certain cases of old fracture of the ankle which came under his care for a reconstructive operation. There was extreme backward displacement of the foot, a condition which he had not previously met and could not find described. The lesion had been overlooked and left unreduced by skilled surgeons despite good radiograms. Not only is the lesion not a simple variant of a Pott's fracture, but the attempt to treat it as such is disastrous in a large percentage of cases. A Pott's fracture is bad enough with two sides of the articular mortise gone, but when the astragalus is driven behind the mortise and deprived not only of lateral support but of any vertical bearing the condition is apt to be hopeless unless properly treated. A twist is usually given as the cause of the injury. One patient slipped on the edge of a mat while wrestling. Another twisted her foot outwards as she stooped from her chair to pick up a rolling spool, a rug slipping under her foot. Apparently an outward and backward twist of the foot is usual, and the fracture takes place while weight is borne on the ball of the foot. Reduction is simple if the lesion is understood. All that is necessary is forward traction with the muscles relaxed in moderate plantar flexion. Having thus brought about the reduction in maximum dorsal flexion it must be held in plaster. If the lesion is not understood the results are bad unless spontaneous reduction occurs. If reduction, spontaneous or operative, is accomplished

the results are excellent and not inferior to those of Pott's fracture. The after-treatment is the same as in this fracture, except that early movement is necessary, but no weight should be borne on the foot for at least seven or eight weeks. The important thing is to know of and look out for this not uncommon and neglected lesion.

NON-PANEL PRACTITIONERS AND INSURANCE ACT CERTIFICATES.

THE questions raised in letters to THE LANCET of Jan. 23rd with regard to certificates of illness given by medical men not upon the panel, and not attending patients who have made their own arrangements for medical benefit, are dealt with in Circular A.S. 161, issued by the Insurance Commissioners, the gist of which is that in the cases referred to Form Med. 40 is not applicable, and it should not be used or asked for. The Commissioners, however, "desire to point out in the clearest terms that insured persons do not disqualify themselves from receiving sickness benefit by obtaining their certificates from doctors attending them in a private capacity." The following passage may be quoted:—

Though a society must distinguish these certificates, it must give them due consideration. A society is not entitled to refuse to receive and consider, in connexion with a claim to benefit, certificates not given under the Medical Certification Rules. On the contrary, a society is bound to take into due consideration any medical certificate put forward in support of a claim. This obviously does not mean that benefit must be paid on every certificate. The society has a responsibility which it is bound to discharge, and every certificate must be considered on its merits. Even where a certificate is on the official form and signed by a panel doctor in the ordinary way, the society should, of course, not pay without consideration. It should consider the certificate and decide whether it affords sufficient evidence for payment or whether further information is desirable, arranging special sick visiting or referring the case to a medical referee as may be required. And where the certificate is not on Form Med. 40 (and is therefore the certificate of a doctor who has attended the member in a private capacity), inquiries must often be needed which the understandings embodied in the Medical Certification Rules render unnecessary in cases certified under those rules.

The attitude of the Commissioners would appear to be one of toleration rather than encouragement of insured persons who show their independence by employing their own medical attendants, and who thus increase the funds available for insurance without deriving any "medical benefit" from them. It is to be regretted that means should not have been devised whereby all medical men certifying should, so to speak, meet on equal terms, writing their certificates upon forms that would make no distinction between the panel and the non-panel practitioner, and subject alike to penalties in respect of any certificate improperly given.

A CASE OF TRICHOCEPHALUS DISPAR.

THE presence of this parasite in the body is difficult to detect; the worm itself, too, is very hard to eradicate. Most characteristic of infection with this small whip-like worm, which buries its more slender extremity deeply into the intestinal mucosa, is the presence in the faeces of the ova which it passes. These are oval with a dark crenated "shell," and have a rounded knob at each end. They are passed in large numbers; they must, however, be carefully sought for, and it is

wise to wash the faeces through muslin. A case of this condition is described by Dr. Henry C. Drury in the *Dublin Journal of Medical Sciences* for March, 1915. The boy was aged 12, and his appearance suggested Hodgkin's disease because of the great enlargement of the glands in the neck and anaemia. He looked wretchedly ill. He had, however, a voracious appetite, though very constipated. Often there was abdominal pain. The blood examination showed a positive Wassermann reaction; there were also, and this was significant, 10 per cent. of eosinophiles in the blood count. This suggested "intestinal worms," and after a dose of santonin an ascaris lumbricoides was voided. Careful microscopical examination of the faeces showed the ova of trichocephalus dispar as well. After many drugs had been tried for this parasite and proved of no avail the operation of appendicostomy was performed. Through this route the colon was irrigated with thymol emulsion and also infusion of quassia, but no result was gained until, finally, a soap-and-water enema, two pints in quantity, resulted in the passage of a copious stool in which were found about a dozen of the parasites. Following this improvement and recovery were uninterrupted. After irrigation of the colon with infusion of quassia at intervals for a few days the wound was closed. Treatment with salvarsan cured the glandular condition. Reference to the literature shows examples of two other cases in which the parasites were found at operation to be in the appendix itself. Though in the present case this was not so, the symptoms at times very much simulated appendicitis.

THE RESULTS OF ANTIMALARIAL PROPHYLAXIS IN ITALY.

FOR the last two years, in face of a slight increase in the mortality from malaria, a certain amount of pessimism has been rife in Italy asserting that the hygienic measures hitherto adopted against that disease have reached their limit, and uttering a warning note that radical results are not possible without a profound transformation of the mosquito-ridden soil. Some observers think that the malarial parasite exists not only in malaria-infected man but also in some other animal, so that the infection of the transmitting mosquito arises not only from the gametiferous man but also from these other animals which harbour the virus. In a recent issue of *Il Morgagni* Dr. E. Bertarelli, professor of hygiene in the University of Parma, draws attention to the fact that the mortality in 1912 again reached a lower figure, the lowest hitherto observed since the mortality returns have been published. In ten years these figures had declined from more than 15,000 deaths to 3000 with absolute regularity, which is in itself proof of the efficacy of the measures adopted. The figures also show that the diminution of mortality again recorded for 1912-13 coincides with an increase in the consumption of quinine provided by the State, while there was also during the same period an increase in the amount of quinine sold privately in the country. A connexion between these facts may logically be assumed, and it is difficult to explain in any other way the reappearance of a decreasing mortality. Professor Bertarelli argues that if gametiferous human beings are the only source of infection for the mosquitoes it would follow that if these sources

are eradicated malaria would cease by automatic necessity. With more assiduous administration of quinine fewer gametiferous beings must be formed and the old stock must be fatally exhausted in a certain number of years by the necessary reduction which death causes. These considerations, taken in conjunction with the reappearance of the diminishing mortality, suggest that apart from human beings no other sources of malaria exist. The author does not deny that the use of mechanical means of defence and the destruction of the mosquitoes have been attended with conspicuous success, but he points out the difficulties inseparable from completely satisfactory achievement—for example, the destruction of hibernating mosquitoes, chiefly females, which are found in a condition of immobility in crevices and on walls. He is, however, strongly of opinion that the free consumption of quinine in malarious districts is the weapon which has given the most certain and rapid results.

THE library and offices of the Royal Society of Medicine will be closed for the Easter holidays from Thursday next, April 1st, to Tuesday, April 6th, both days inclusive.

ASYLUM REPORTS.

Suffolk District Asylum (Annual Report for the Year 1913).

—The total number of cases under treatment during the year was 1107, the average daily number resident being 917. The total number of admissions was 209 and the discharges amounted to 101. The recovery rate calculated on the net admissions was 15·8 per cent. There were 114 deaths, representing 12·4 per cent. on the average number resident. Of the total deaths 18·4 per cent. were due to senile decay, 19 per cent. to some form of tuberculous disease, and 10·5 per cent. to general paralysis of the insane. Dr. J. R. Whitwell, the medical superintendent, in making some general remarks, refers to the fact that it has been decided by the present lunacy law that if a man is well-to-do he can go to an institution for the treatment of mental disease and become a voluntary boarder, but that if he is a poor man he must go on from bad to worse, and even to attempted suicide (or whatever ultimate tendency his case has), before he can be brought under proper treatment. It is quite clear to all thinking persons dealing with mental disease that some greater latitude must sooner or later be given by the law, especially in the case of public institutions, if such institutions are to give their best service to, and perform their true function in, the community, and some greater degree of confidence must be placed in and some discretionary power given to the medical staff of what really is and should be called the "mental hospital" of the county than is either given or implied by the present Lunacy Act.

West Riding Pauper Lunatic Asylum, Wakefield (Annual Report for the Year 1913).—The total number of patients under treatment was 2500, the average daily number resident being 2068. The admissions amounted to 462 and the discharges to 155, of which 119 were recoveries, making a percentage of 25·76 on the total admissions. There were 241 deaths, making a rate of 11·65 per cent., estimated on the average number resident. Post-mortem examinations were performed in 85 per cent. of the deaths. During the year out-of-door treatment of the patients has been continued with satisfactory results. During the greater part of the year the whole of the recently admitted sick and infirm patients are kept in bed out of doors in the open air from morning until night, and meals are provided out of doors for the whole of the patients in the institution. The general health of the institution has been satisfactory, but 100 cases of dysentery have occurred during the year, of which 20 died. This epidemic of dysentery made the routine work of the pathological department very heavy. Numerous Wassermann reactions have been

performed and all the newly bought cattle tested with tuberculin. Dr. J. S. Bolton, the medical superintendent, draws attention to the importance of the educational work of the asylum, where the whole of the training for the diploma in psychological medicine of the University of Leeds is carried out. Dr. Bolton has been engaged throughout the year in completing a work on cerebral function, and his assistants, Dr. H. Devine, Dr. Alice Babington, and Dr. W. Robinson, and Mr. Harold S. Gettings, the pathologist, were all engaged in scientific research. — *Stanley Hall.*—Twelve new cases have been admitted during the year, and of these 6 attend school. During several months of the year the whole of the boys have lived outside, and the lessons have been conducted in the open air. The out-patient department continues in a flourishing condition.

The Retreat, York (Annual Report for the Year 1913).

—The total number of cases under treatment during the year was 259, of which 26 were voluntary boarders. The average daily number resident was 181·37 certified patients and 5·12 voluntary boarders. There were admitted 52 certified cases, and of these 48 were direct admissions. In no less than 14 of the new cases no cause whatever for the insanity could be assigned, in spite of the care taken in studying their history. The discharges numbered 37, of which 15 were recoveries. There were 8 deaths. Dr. Bedford Pierce, the medical superintendent, refers to the treatment of incipient insanity, and points out that as things are at present little or nothing can be done for persons threatened with a mental breakdown; the general hospitals have no beds for such and the public asylums cannot admit them unless certified as insane. The county and borough asylums in England and the district and parochial asylums of Scotland are not permitted to receive voluntary boarders. Expert treatment is therefore unattainable by the poor until the illness has become so pronounced that the patient can be certified as insane. Those persons who are on the verge of a breakdown, and who can afford to pay, can apply for admission as voluntary boarders to hospitals for the insane and licensed houses; but it commonly happens that the patients most needing treatment are not able to make up their minds to apply or decline to entertain the idea. Even when persuaded to come under care voluntarily many do not stay long enough to derive any benefit. It therefore seems desirable that besides ordinary certified patients and voluntary boarders there should be a legally recognised class which for the present purpose we may call "notified" patients. Persons so received would be detained for a strictly limited period, say three months, with a power to extend to six months in all, provided the facts of the case were fully notified to the Board of Control, and such medical statements supplied as the Board might require. It is assumed that notified patients would be visited periodically by members of the Board of Control, that no restrictions would be placed upon their correspondence, and that in other ways ample safeguards would be provided against abuse. But in addition to this it is much to be desired that early and undeveloped cases should be received temporarily into any institution for the insane approved by the Board of Control without the necessity for formal certification.

Waterford District Lunatic Asylum (Annual Report for the Year 1913).

—The number resident in the asylum on Dec. 31st, 1913, was 642, which was 17 more than at the beginning of the year. The average daily number resident in the asylum was 632 and the total number of admissions was 65, which is the smallest number for the past 30 years and well below the average for the past 10 years. The principal assigned causes of insanity in those admitted were as follows: Hereditary predisposition, 22 cases; mental stress or worry, 19; alcoholic excess, 11; mental deficiency, 6. The number discharged was 26, with a recovery rate calculated on the number admitted of 32·3 per cent., which is the lowest rate since 1908. There were 22 deaths, making a proportion of 3·5 per cent. on the average daily number resident. This is 3·5 below the average death-rate of the other Irish asylums. Tuberculous disease accounted for 18·1 per cent. of the total number. If the foregoing figures are closely examined it will be seen that although there has been an increase of 17 patients during the past year this is due almost entirely to the accumulation of patients. There has been a marked diminution in the number admitted, but at the same time the number discharged and died have declined.

The Coppice Mental Hospital for the County and City of Nottingham (Annual Report for the Year 1913).—The total number of cases under treatment during the year was 114, the average daily number resident being 89. The number of cases admitted was 24, and in 29 per cent. of these a definite neurotic history was ascertained. There were 18 discharges, with 10 recoveries, giving the good percentage of 43.47 on the admissions. There were only 3 deaths, making the low proportion of 3.36 per cent. on the average number resident. One patient was admitted as a voluntary boarder. Dr. D. Hunter, the medical superintendent, remarks that it is to be regretted that more patients do not take advantage of this method of obtaining treatment when a mental breakdown is felt to be impending. At this early stage a course of treatment would in many cases relieve or prevent the attack of insanity, and the patient would be spared the stigma of certificates. A much-needed addition to the curative resources of the hospital was made in the shape of a shelter for the out-of-door treatment of acute cases.

Glamorgan County Lunatic Asylum, Bridgend (Annual Report for the Year 1913).—The total number of cases under treatment during the year was 2106, the average daily number resident being 1784.9. There has been overcrowding to the extent of 123 males and 13 females as regards dormitory space, and 194 males and 103 females as regards day-room space. The total number of admissions was 353, of which 339 were direct. The most obtrusive feature in the etiological tables is the fact that cases in which alcohol is ascribed as principal or contributory cause are 32 less than last year, the percentage being 12.4, as compared with 21.0. The discharges numbered 132, of which 91 were recoveries. The recovery rate on the total admissions is 4 per cent. lower than last year. The exceptionally low death-rate of 8.1 per cent. on the average daily number on the register has not been recorded since the year 1896. The disease responsible for the largest number of deaths is general paralysis of the insane, the proportion being 23.4 per cent. Deaths due to tuberculous diseases are less numerous than last year, and are 14.5 per cent.

Down District Lunatic Asylum (Annual Report for the Year 1913).—The total number of cases under treatment during the year was 900, the average daily number resident being 770. The total number of admissions was 139. With regard to the assigned causes and associated factors, it is interesting to note that passing events influence very largely the manner in which current insanity manifests itself. During the past year contemporary insanity has been tinged by occurrences more or less ephemeral which have taken place. In cases of delusions, the "voices" are now definite commands of opposing factions of political and sectarian strife, the "vague fears" are the acute terrors of "civil war," the "unknown enemies" are "Orangemen" or "Hibernians," as the case may be. In some cases undoubtedly this strain was the exciting cause of the breakdown; in others it unquestionably shaped the form of the attack which would have occurred in any event. At all periods of exceptional popular emotional waves the lunatics of the period reflect in their delusions the prevailing ideas. The discharges numbered 73, with a recovery rate on the admissions of 44.6 per cent. The deaths amounted to 52, making a rate of 6.8 per cent. on the average number resident.

City of Cardiff Mental Hospital (Annual Report for the Year 1913).—The total number of cases under treatment during the year was 916, the average daily number resident being 710. The direct admissions amounted to 170, and there were 76 transfers from other asylums. A history of heredity of some kind was elicited in 47 per cent. of the direct admissions. The discharges numbered 88, with a recovery rate calculated on the direct admissions of 35.88 per cent. There were 97 deaths, and necropsies were held in 91 cases. Tuberculosis was directly responsible for deaths in 17.52 per cent., and tubercle was found in 4 others. General paralysis was the cause of death in 18.55 per cent. of the cases. Dr. E. Goodall and Dr. H. A. Schölberg have carried out research work in connexion with the Wassermann reaction, the results of which were communicated at the last International Congress of Medicine in London.¹ They have also investigated the question of the production of specific antiserum in rabbits by injecting them with serum

from patients suffering from dementia paralytica and dementia præcox. A very large number of rabbits were injected, but only in four or five was a precipitin produced which was capable of causing abundant precipitate in the corresponding human serum in a dilution of 1:1000. Their experiments showed that the antiserum produced by injection of a rabbit with serum from a case of a given kind of insanity is not specific as far as precipitin formation is concerned. The method cannot therefore be used for diagnosis. Dr. Goodall and Dr. Schölberg are also engaged in examining the brain cortex of general paralytics and the blood of these and of cases of the disease known as dementia præcox for the possible presence of organisms growing anaerobically. Dr. Goodall has been also testing the treatment of cases of acute and recent insanity with leucocytic extract. He has found that large doses of thyroid (40-60 grains a day) have given satisfactory results in certain cases of an "anergic" type, and have sometimes reduced the number of fits in cases of epilepsy. He considers that the whole subject of metabolism in the psychoses is in urgent need of examination. The dietetic treatment of epilepsy has also been investigated. Dr. Stanford, the research chemist, has been studying the cerebro-spinal fluid of the insane from a quantitative point of view. Mr. Barton White has continued his investigations of the bacteriology of intestinal contents, and also a bacteriological examination of the urine in general paralysis. Dr. D. J. Jackson has made a large number of qualitative leucocytal counts in certain typical cases of acute insanity.

Staffordshire County Mental Hospitals at Stafford, Burslem, and Cheddleton (Annual Report for the Year 1913).—The total number of cases under treatment during the year was 1117, the average daily number resident being 888. The total number of admissions was 248, and the principal causes assigned for the mental trouble were as follows: Heredity, 53; alcohol, 25; epilepsy, 21; mental stress, 18; senility, 14; puerperal state, 5; climacteric, 4; and congenital mental deficiency, 3. There were 113 discharges, with a recovery rate of 23.7 on the admissions. There were 106 deaths, giving a proportion of 11.93 per cent. on the average daily number resident. Phthisis was responsible for 28 of the deaths. Necropsies were only made in 56 instances. The question of providing verandahs for the better treatment of tuberculous cases has been under the consideration of the committee for some time.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The undermentioned have been granted temporary commissions as Surgeon in His Majesty's Fleet:—Charles Williams Lewis and John Francis Pace.

The following appointments have been notified:—Surgeons: H. W. Nicholls to the *Faulknor*; and F. H. Stephens to the *Pembroke*, additional. Temporary Surgeons: J. F. McQueen to the *Victory*, additional, for Royal Naval Division Depot at Crystal Palace; D. Sutherland to the *Vernon*; M. B. Hay, D. R. Bedell-Sivright, N. P. Price, J. Bostock, F. H. Rees, G. L. Ritchie, E. M. Lauderdale, and L. S. Fry, all to the *Victory*, additional, for Royal Naval Division.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Robert Joseph Willan has been specially promoted to the rank of Staff-Surgeon for distinguished service (dated March 5th).

The undermentioned Surgeons have been promoted to the rank of Staff-Surgeon: Reginald John Edward Hanson (dated Dec. 23rd, 1911). Edward John Steegman (dated Feb. 13th, 1912). Harry Reah (dated May 16th, 1913). William Edmund Harker (dated August 3rd, 1913).

Staff Surgeon Francis John Hannan has been promoted to the rank of Honorary Staff-Surgeon (dated March 17th).

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Albert L. F. Bate, from Royal Army Medical Corps, to be Colonel (dated March 1st).

ROYAL ARMY MEDICAL CORPS.

Temporary Captain Percy Sargent is granted temporarily the honorary rank of Lieutenant-Colonel (dated Dec. 13th, 1914).

Temporary Captain Gordon M. Holmes is granted temporarily the honorary rank of Major (dated Dec. 13th, 1914).

The undermentioned Temporary Lieutenants to be Temporary Captains:—Isaac Jones (dated March 20th); William Parry Morgan and Charles W. G. Bryan (dated March 21st); and Fergus Armstrong (dated March 23rd).

¹ THE LANCET, Dec. 26th, 1914, p. 1451, also Dec. 5th (p. 1287), 12th (p. 1343), and 19th (p. 1397).

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers:—Captains to be Majors: Charles Gibbons Seymour, Thomas Corrie Rutherford, Ernest Charles Taylor, and Alfred Whitmore (dated Jan. 31st).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant William K. Campbell is confirmed in his rank.

TERRITORIAL FORCE.

Army Medical Services.

Lieutenant-Colonel Charles Averill, from Sanitary Service, to be Deputy Assistant Director of Medical Services, Welsh Division (dated Feb. 17th). Captain Charles S. Wink, from Attached to Units other than Medical Units, to be Deputy Assistant Director of Medical Services, East Anglian (Reserve) Division (dated Feb. 14th).

Royal Army Medical Corps.

South-Eastern Mounted Brigade Field Ambulance: Major (Honorary Lieutenant in the Army) Lewis Harcourt Coles, Reserve of Officers, Retired List, Territorial Force, to be Transport Officer, with the honorary rank of Captain (dated March 18th).

Yorkshire Mounted Brigade Field Ambulance: Surgeon-Captain Robert A. Draper, from East Riding of Yorkshire Yeomanry, to be Major (temporary) (dated March 14th).

3rd East Lancashire Field Ambulance: Lieutenant Charles Bertram Marshall to be Captain (temporary) (dated Feb. 27th).

3rd North Midland Field Ambulance: Lieutenant-Colonel Lewis Walter Pocket, Retired List, Territorial Force, to be Lieutenant-Colonel (temporary) (dated Feb. 22nd).

1st Northern General Hospital: Major Frederick C. Pybus to be seconded (dated March 12th).

Welsh Border Mounted Brigade Field Ambulance: Frank Leslie Newton to be Lieutenant.

1st Eastern General Hospital: Paul Norman Blake Odgers to be Captain, whose services will be available on mobilisation.

Northumbrian Casualty Clearing Station: Charles Frederick Morris Saint to be Lieutenant.

Attached to Units other than Medical Units.—To be Majors: Captain (Honorary Lieutenant in Army) Michael J. Mahoney and Captain Peter M. Dewar. Captain John Orton, from the Territorial Force Reserve, to be Captain. Donald Peter MacLaren Farquharson (late Lieutenant 5th Volunteer Battalion, Argyll and Sutherland Highlanders), to be Captain (temporary). To be Lieutenants: Thomas Willoughby Cole, Ismay Donald Stubbs, and Lieutenant Duncan F. Macrae, from London Mounted Brigade Field Ambulance.

DEATHS IN THE SERVICES.

Deputy Inspector-General Charles Alexander Lees, R.N., recently, in his 81st year. He served in the Baltic operations in 1855 (medal) and in the China war, 1857-59, being in charge of the garrison of Macao Fort, Canton River (China medal).

PROMOTION IN THE ROYAL ARMY MEDICAL CORPS.

The Under Secretary of State for War has sent the following reply in answer to a question by Sir Clement Kinloch-Cooke, M.P.: "In reply to your letter, in which you raised the question of the promotion of junior officers in the Royal Army Medical Corps, I am glad to be able to inform you that it has now been arranged that all the lieutenants in the Royal Army Medical Corps should be promoted captains."

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The December issue of this journal, just published, closes the twenty-third volume. The first article is a continuation of the joint communication on the Trypanosome Causing Disease in Man in Nyasaland, by Sir David Bruce, Major A. E. Hamerton, Captain D. P. Watson, and Lady Bruce, quoted from the Proceedings of the Royal Society. In Notes on the Bacteriology of Wounds, by Lieutenant T. H. Just, Demonstrator of Pathology at St. Bartholomew's Hospital, giving a short series of cases examined in No. 12 General Hospital at Rouen, the conclusion is drawn that the infection of wounds is in the main one of low virulence, the damage of the tissues being chiefly effected by the concussion of the shell or bullet, as the case may be, and not by the infecting micro-organism. Major C. F. Wanhill has a useful article on Incineration and Incinerators as Applied to Cantonments in India; Captain G. K. Aubrey describes a short form of stretcher for use in trenches¹; and there is an interesting communication from Dr. Moraes Manchego, Médecin de l'Armée portugaise, on Statistiques Sanitaires; Leur Importance pour l'Etude des Conditions Physiques et Morales des Troupes. Colonel R. H. Firth takes for the subject of his note-book talks Phantom Matter, and explains the present position or meaning of the recently acquired facts concerning the radio-elements. He has endeavoured to use simple language, but, as he points out, it may be stiff reading for some.

¹ THE LANCET, Dec. 26th 1914, p. 1488.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8582 births and 6714 deaths were registered during the week ended Saturday, March 20th. The annual rate of mortality in these towns, which had declined from 20.7 to 19.7 per 1000 in the four preceding weeks, further fell in the week under notice to 19.3 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first eleven weeks of the current quarter the mean annual death-rate in these towns averaged 19.5, against a corresponding rate of 20.3 per 1000 in London. The annual death-rate last week ranged from 8.2 in Gloucester, 9.5 in Lincoln, 9.7 in Barnsley, 10.0 in Dudley, and 10.3 in Ilford and in Gillingham, to 25.3 in South Shields, 26.4 in Preston, 26.8 in Wigan, 27.6 in Merthyr Tydfil, and 28.0 in Darlington.

The 6714 deaths from all causes were 149 fewer than the number in the previous week, and included 739 which were referred to the principal epidemic diseases, against numbers increasing from 511 to 657 in the five preceding weeks. Of these 739 deaths, 421 resulted from measles, 151 from whooping-cough, 63 from infantile diarrhoeal diseases, 61 from diphtheria, 29 from scarlet fever, and 14 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2.1, or 0.2 per 1000 higher than that recorded in the previous week. The deaths attributed to measles, which had increased from 207 to 373 in the five preceding weeks, further rose to 421 last week, and caused the highest annual death-rates of 3.5 in Stockton-on-Tees, 3.8 in Wolverhampton, 4.1 in St. Helens, 5.1 in Enfield, 5.4 in Cambridge, 5.7 in West Hartlepool, 6.1 in Smethwick, 6.8 in West Bromwich, and 8.8 in Darlington. The deaths referred to whooping-cough, which had been 111, 110, and 120 in the three preceding weeks, further rose to 151 last week, and included 41 in London, 9 in Liverpool, 8 in Bristol, 5 in Wigan and in Leeds, and 4 each in Portsmouth, Southampton, Hull, and Merthyr Tydfil. The fatal cases of diarrhoea and enteritis (among infants under 2 years), which had been 75, 71, and 77 in the three preceding weeks, fell to 63 last week, of which 15 were registered in London, 5 in Leeds, and 3 each in Birmingham and Sheffield. The deaths from diphtheria, which had declined from 80 to 51 in the four preceding weeks, rose to 61 last week, and included 17 in London, 6 in Birmingham, and 3 each in West Ham, Stoke-on-Trent, Liverpool, and Sheffield. The deaths referred to scarlet fever, which had been 38, 32, and 21 in the three preceding weeks, rose to 29 last week; 6 deaths belonged to London, 3 each to Liverpool and Merthyr Tydfil, and 2 to Darlington. The fatal cases of enteric fever, which had been 13, 10, and 15 in the three preceding weeks, were 14 last week, and included 2 each in London, Liverpool, and Manchester.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5036 to 2850 in the 16 preceding weeks, had further fallen to 2730 on Saturday last; 289 new cases were admitted during the week, against 302, 298, and 275 in the three preceding weeks. These hospitals also contained on Saturday last 1505 cases of diphtheria, 283 of measles, 57 of enteric fever, 19 of whooping-cough, and 3 of small-pox. The 1826 deaths from all causes in London were 32 in excess of the number in the previous week, and corresponded to an annual death-rate of 21.1 per 1000. The deaths referred to diseases of the respiratory system, which had been 476, 468, and 442 in the three preceding weeks, rose to 478 last week, and were 228 above the number recorded in the corresponding week of last year. The deaths from influenza numbered 67, against 83, 48, and 54 in the three preceding weeks.

Of the 6714 deaths from all causes in the 96 towns 199 resulted from different forms of violence and 489 were the subject of coroners' inquests, while 1795 occurred in public institutions. The causes of 48, or 0.7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 67 other smaller towns. Of the 48 uncertified causes of death, 10 were registered in Birmingham, 4 each in Stoke-on-Trent, Liverpool, and St. Helens, 3 in Bootle, and 2 each in Coventry, Warrington, Hull, and South Shields.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1149 births and 936 deaths were registered during the week ended Saturday, March 20th. The annual rate of mortality in

these towns, which had been 21.2, 23.2, and 20.9 per 1000 in the three preceding weeks, further fell to 20.8 per 1000 in the week under notice. During the first eleven weeks of the current quarter the mean annual death-rate in these towns averaged 22.5, against 19.5 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 9.5 in Coatbridge, 13.7 in Falkirk, and 14.9 in Paisley, to 22.6 in Kilmarnock, 23.0 in Hamilton, and 30.0 in Dundee.

The 936 deaths from all causes were 4 fewer than the number in the previous week, and included 139 which were referred to the principal epidemic diseases, against 145 and 131 in the two preceding weeks. Of these 139 deaths, 88 resulted from whooping-cough, 26 from measles, 11 from scarlet fever, 7 from diphtheria, 6 from infantile diarrhoeal diseases, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3.1, against 2.1 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 89, 91, and 87 in the three preceding weeks, were 88 last week, and included 44 in Glasgow, 26 in Dundee, 7 in Edinburgh, and 3 in Greenock. The deaths referred to measles, which had been 8, 21, and 15 in the three preceding weeks, rose to 26 last week, of which 15 were recorded in Glasgow and 9 in Dundee. The fatal cases of scarlet fever, which had been 11, 9, and 13 in the three preceding weeks, fell to 11 last week, and comprised 5 in Glasgow, 3 in Aberdeen, 2 in Edinburgh, and 1 in Kirkcaldy. The deaths attributed to diphtheria, which had been 11, 15, and 10 in the three preceding weeks, further fell to 7 last week, and included 4 in Glasgow and 2 in Aberdeen. The 6 deaths of infants referred to diarrhoea and enteritis were 1 below the average in the three preceding weeks, but showed no excess in any individual town. The fatal case of enteric fever occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 235, 264, and 215 in the three preceding weeks, further fell to 188 in the week under notice, but were 71 above the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 36, against 34 and 23 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 622 births and 558 deaths were registered during the week ended Saturday, March 20th. The annual rate of mortality in these towns, which had been 27.6, 27.4, and 25.9 per 1000 in the three preceding weeks, further fell to 24.0 per 1000 in the week under notice. During the first 11 weeks of the current quarter the mean annual death-rate in these towns averaged 25.8 against corresponding rates of 19.5 and 22.5 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 23.8 in Dublin (against 21.1 in London and in Glasgow), 25.0 in Belfast, 25.8 in Cork, 21.5 in Londonderry, 31.1 in Limerick, and 32.3 in Waterford, while in the 21 smaller towns the mean rate was 20.0 per 1000.

The 558 deaths from all causes were 44 fewer than the number in the previous week, and included 36 which were referred to the principal epidemic diseases, against 36 and 37 in the two preceding weeks. Of these 36 deaths, 14 resulted from whooping-cough, 8 each from measles and scarlet fever, 4 from infantile diarrhoeal diseases, and 2 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1.5, against corresponding rates of 2.1 and 3.1 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 18, 10, and 12 in the three preceding weeks, rose to 14 last week, and comprised 13 in Dublin and 1 in Belfast. The deaths from measles, which had been 8 in each of the three preceding weeks, were again 8 last week, of which 7 occurred in Belfast and 1 in Dublin. The 8 fatal cases of scarlet fever were double the average in the earlier weeks of the quarter, and included 6 in Waterford. The deaths of infants (under 2 years) attributed to diarrhoea and enteritis, which had been 5, 11, and 14 in the three preceding weeks, fell to 4 last week, and comprised 2 in Dublin and 2 in Belfast. The 2 fatal cases of diphtheria were recorded in Dublin and Belfast respectively. In addition to the above deaths a fatal case of typhus was registered in Kilkenny.

The deaths referred to diseases of the respiratory system, which had been 187, 188, and 167 in the three preceding weeks, further fell to 155 in the week under notice. Of the 558 deaths from all causes, 160, or 29 per cent., occurred in public institutions, and 18 resulted from different forms of violence. The causes of 24, or 4.3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0.7 per cent.

VITAL STATISTICS OF LONDON DURING 1914.

In the accompanying table statistics of sickness and mortality in the City of London and in each of the metropolitan boroughs are summarised for the year 1914. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to a rate of 9.0 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding years the rates had been 4.5, 5.1, and 6.7 per 1000 respectively. Among the various boroughs the rates last year ranged from 5.9 in Holborn, 6.4 in Chelsea, 6.8 in Hampstead, and 6.9 in St. Marylebone and in Wandsworth, to 9.8 in Fulham, 10.4 in Hammersmith, 10.8 in Bethnal Green, 11.6 in Southwark, 12.5 in Deptford, and 12.7 in Stepney. The prevalence of scarlet fever showed a further marked increase last year, 25,015 cases being notified during the year, against 10,489, 11,312, and 17,552 in the three preceding years. Among the metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Hammersmith, Fulham, Stepney, Southwark, and Deptford. The Metropolitan Asylums Hospitals contained 4431 scarlet fever patients at the end of last year, against 1878, 2088, and 3810 at the end of the three preceding years; 23,154 new cases were admitted during the year, against 9631, 10,488, and 16,255 in the three preceding years. Diphtheria also was more prevalent than it had been in other recent years; 9118 cases were notified, against 7101 and 7654 in 1912 and 1913 respectively. This disease was proportionately most prevalent last year in Hampstead, Bethnal Green, Stepney, Greenwich, and Woolwich. The number of diphtheria patients admitted into the Metropolitan Asylums Hospitals during the year was 8444, against 6184 and 6814 in the two preceding years; the number of patients remaining under treatment at the end of the year was 1663, against 959 and 1099 at the end of the two preceding years. The prevalence of enteric fever showed a slight increase over that in preceding years, 779 cases being notified against 704 and 758 in the two preceding years. Among the several boroughs this disease was proportionately most prevalent in Chelsea, the City of Westminster, St. Marylebone, Holborn, and Lewisham. The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during the year was 470, against 381 and 415 in the two preceding years; 68 cases remained under treatment at the end of the year, against 37 and 51 at the end of the two preceding years. The greatest proportional prevalence of erysipelas occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, Southwark, and Deptford. The 393 cases of puerperal fever notified during the year included 33 in Fulham and in Stepney, 31 in Wandsworth, 29 in Southwark, 25 in Islington, 24 in Camberwell, and 23 in Poplar and in Lambeth. Of the 73 cases of cerebro-spinal meningitis 9 belonged to Poplar, 7 to Islington, 6 to Southwark, and 5 each to Bermondsey and Lambeth. The 93 cases of poliomyelitis included 27 in Stepney, 10 in Lambeth, 8 in Islington, 8 in Poplar, 5 in Hackney, and 5 in Camberwell.

The mortality figures in the table relate to the deaths of persons actually belonging to the several boroughs, and are obtained by distributing the deaths in institutions among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs. During last year the deaths of 64,994 persons belonging to London were registered, equal to a corrected death-rate of 14.4 per 1000; in the three preceding years the rates were 15.8, 14.3, and 14.2 per 1000 respectively. Among the several boroughs the lowest death-rates last year were 10.7 in Lewisham, 11.0 in Hampstead and in Wandsworth, 12.5 in Stoke Newington, and 12.9 in Paddington and in Chelsea; the highest rates were 17.3 in Stepney, 17.4 in Bermondsey, 17.9 in Southwark, 19.4 in Finsbury, and 19.6 in Shoreditch. The deaths from all causes included 6503 from the principal infectious diseases; of these, 1385 resulted from measles, 316 from scarlet fever, 706 from diphtheria, 918 from whooping-cough, 147 from enteric fever, and 3031 from diarrhoea and enteritis among children under 2 years of age. The death-rates from these diseases in the aggregate ranged from 0.5 in Hampstead and in the City of London, 0.6 in the City of Westminster and in Stoke Newington, and 0.7 in Kensington, in Chelsea, and in Lewisham, to 2.1 in Poplar and in Bermondsey, 2.2 in Southwark, 2.3 in Stepney, 2.6 in Bethnal Green, 2.7 in Finsbury, and 3.1 in Shoreditch. The 1385 fatal cases of measles were 665 below the corrected average number in the five preceding years; this disease was proportionately most fatal in Finsbury, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey. The 316 deaths from scarlet fever were 72 in excess of the corrected average number; the greatest proportional mortality from this disease was recorded in Kensington, Fulham, Stepney, Southwark, and Camberwell. The 706 fatal cases of diphtheria were 200 above the corrected average number; the highest death-rates

† The death-rates are corrected for variations in sex and age constitution of the populations of the several boroughs, the population of England and Wales, being taken as the standard.

from this disease were recorded in Bethnal Green, Stepney, Poplar, Southwark, Deptford, and Woolwich. The 918 deaths from whooping-cough were 164 fewer than the corrected average number; this disease was proportionally most fatal in Fulham, Islington, Finsbury, Shoreditch, Bethnal Green, Stepney, and Southwark. The 147 fatal cases of enteric fever were slightly in excess of the corrected average number; the greatest proportional mortality from this disease occurred in Fulham, the City of Westminster, Holborn, and the City of London. Diarrhoea and enteritis among children under 2 years of age was proportionally most fatal in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last year from the principal infectious diseases, excluding diarrhoea, was 12·3 per cent. below the average.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ulster Hospital for Women and Children.

At the annual meeting of the friends of this institution held on March 18th it was reported that during the 12 months under review 4028 new cases had been treated in the different departments, and that 433 operations had been performed. Mr. S. T. Irwin has been appointed full surgeon in place of Mr. A. B. Mitchell resigned, and Dr. T. S. S. Holmes has been selected as gynaecological surgeon in room of Dr. Marion B. Andrews, resigned. Financially the total expenditure was £2034 2s. 2d., while the income amounted to £2004 14s. 6d., and with the balance carried forward from 1913 the hospital starts the year 1915 with a credit of £389 8s. 11d.

Ulster Medical Society.

At a meeting of the Ulster Medical Society held on March 18th Dr. T. S. Kirk read a paper on the Surgical Aspects of Hyperacidity. A discussion followed, which was made much more interesting and practical by the relation of the personal experience of two medical men who had themselves undergone surgical operation for gastric and duodenal ulcers.

The Drink Question.

The heads of the four largest religious bodies in Ireland (Roman Catholic, Protestant Episcopal, Presbyterian, and Methodist) have sent to the Prime Minister a letter expressing the strong feeling throughout the country that the example set by Russia and France and, in a smaller degree by Germany, in dealing with the drink traffic should be followed by Great Britain and Ireland. They urge the closing of public-houses and clubs on Sunday, the abolition of the *bona-fide* Travellers Act, the prohibition of the sale of drink after 1 P.M. on Saturday and 6 P.M. on other days, and the doing away with "wet" canteens in military camps.

Cerebro-spinal Meningitis.

From Dec. 8th, 1914, to March 20th, 1915, there have been received into Purdysburn Municipal Fever Hospital, Belfast, 22 cases of cerebro-spinal meningitis ("spotted fever"). Of these, 12 were civilians and 10 came from the following military camps—viz., 7 from Randalstown, 2 from Clondeboye, and 1 from Lurgan. Of these 22 cases, 5 have died—that is, a mortality of almost 23 per cent.

The late Dr. Timothy Crowley.

Dr. Timothy Crowley, who died suddenly on March 7th, was educated at Queen's College, Cork, where he was a medical scholar and prizeman and graduated M.D., M.Ch. in 1872. He was medical officer of the Clonmoyle Dispensary District and the

senior medical officer of the Macroom Union. With his professional brethren he was very popular. By his death a notorious murder case at Coachford, Cork, is recalled, for it was chiefly owing to the medical evidence of Dr. Crowley and Professor C. Y. Pearson that the murderer, a retired army surgeon, named Cross, was brought to justice for poisoning his wife.

March 22nd.

INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Hospitals for Wounded Indian Soldiers.

Lucknow and Allahabad are amongst the stations at which special hospital accommodation has been made for the wounded Indian soldiers from the front, the arrangements being under charge of Surgeon-General H. G. Hathaway, Deputy Director of Medical Services in the 8th (Lucknow) Division. At Lucknow an Indian Troops Hospital has been fitted up in cantonments for 207 cases, while part of King George's Civil Hospital, to accommodate 50 cases, has been allotted for wounded Indian troops. At Allahabad preparations have been made for the reception of 75 cases altogether in two different hospitals, one in the Indian infantry lines and the second in the Indian cavalry lines. In the fitting up of the hospitals assistance was given by the Lucknow and Allahabad Committees of the St. John Ambulance Association, who have provided many articles to add to the comfort of the sick soldiers. Already two batches of cases have been received at Lucknow. A few weeks ago 46 from France and the Persian Gulf arrived, while on Monday last there came 118 further cases, chiefly from France, and including five Indian officers; both batches are comfortably installed, the first at King George's Hospital and the second at the Indian Troops Hospital. European and Indian residents in Lucknow have vied with each other in lending their motor-cars for the purpose of transport from the station to the hospital, while for lying-down cases ambulance tongas were available. The 118 who came on Monday, March 8th, arrived at night, and hot milk was given to them at the station before they started on their journey to hospital. Most of them, as already mentioned, received their injuries in France and are suffering from rifle or machine-gun wounds. There are also a number of cases of frost-bite.

Arrival of Wounded Soldiers at Bombay.

The hospital ship *Sicilia* arrived in Bombay on Friday, March 12th, with several hundred wounded Indian soldiers who have been fighting in France and Belgium. All the men had been in hospital in England and many of them were convalescent. As the ship entered the dock these latter crowded on to the rails anxious to get the first glimpse of their native land. A few amongst them had crutches or sticks, and some had an arm in a sling, but the majority showed no signs of the strenuous times they had gone through, if we except the peculiar look which is to be seen in the eyes of all soldiers who have been at hand-grips with death on the battle-field. The diversity of costumes worn by the men was great, each man having been allowed apparently to dress as his fancy dictated. Some had on well-worn khaki uniforms, others wore the *dhotar* or *kamis*, others again were attired in a mixture of Indian and European garb, and there was one man whose costume consisted of a pair of

army boots, socks, underpants, and vest, with a knitted cap on his head to complete the effect. In headgear, too, there were many different styles, ranging from the khaki-coloured pugree to the slouch hat of the Gurkha, while two young Gurkhas were proudly wearing the regulation British Army field cap. The serious cases were removed by the local Ambulance Corps, consisting mainly of the Parsi Overseas Brigade, to the Lady Hardinge War Hospital, or the Marine Lines Hospital, while the convalescents went to up-country stations in the ambulance trains.

Sanitary Reforms in Bombay.

After an interval of eight months the Bombay Government have issued their resolution reviewing the recommendations contained in the Government of India resolution on Indian sanitary policy, which was issued so far back as May 23rd, 1914.¹ The wheels of the administrative machinery, no doubt, move very slowly, and it is rather late in the day to issue orders on Jan. 7th, 1915, that the Indian Government's resolution of May last "should be forwarded for information to the Sanitary Commissioner for the Government of Bombay; the Surgeon-General with the Government of Bombay," and so on. It is pointed out that the suggestion of the Government of India as to the desirability of health officers and sanitary inspectors being attached to all municipalities is being adopted in many places in this Presidency. The Government have sanctioned grants-in-aid towards the cost of the entertainment of these officers in accordance with the scheme laid down by the Government of India. The Sanitary Commissioner has also submitted proposals for the regrouping of municipalities, for the classification of health officers and sanitary inspectors, and for the improvement of their pay and prospects. These proposals are under the consideration of the Government. As to the suggested constitution of provincial sanitary boards composed of officials and non-officials, such a board has recently been appointed, or rather reconstituted, in this Presidency, and has been authorised to sanction projects costing up to Rs.20,000, and to make non-recurring grants up to Rs.10,000. The Government of India laid down that every facility should be provided for people to obtain protection against plague through inoculation. The Local Government, it would appear, have been employing 24 sub-assistant surgeons for inoculation work in the Presidency. Besides this, a grant of Rs.1000 is placed annually at the disposal of the Surgeon-General to meet expenditure in connexion with antiplague inoculation at the different hospitals. As regards special anti-tuberculosis measures, we are told that the question of the establishment of tuberculosis dispensaries and separate wards for tuberculous patients is under consideration of the Government. Special attention was invited by the Government of India to the importance of making sanitary surveys on broad lines, and it was suggested that systematic working plans should be drawn up with a view to mapping out the sanitary conditions of all important towns and localities in which sickness or mortality is abnormal. The Local Government have instituted a few such surveys, mostly malarial, in places like Karachi, Kharaghoda, Salsette, and in Kanara district. Apart from these surveys we are told that the Government have

under consideration proposals for the appointment of district health officers who will relieve and enable the Deputy Sanitary Commissioners to undertake systematic sanitary surveys of the urban areas in their charges. The question of having in every important municipality a small, well-built segregation hospital is also sympathetically viewed by the Government, as also the need of adopting organised measures for the diffusion of elementary knowledge of the more common infectious diseases. The question of the contamination of milk-supply is stated to be engaging the attention of Government.

Plague Prevention in Lahore.

The health officer of Lahore has put forward a scheme for cleansing the city with a view to the prevention of plague. He suggests that a scheme of house-to-house cleansing should be organised, and, to start with, five gangs of ten men each should be engaged to undertake the work of cleansing. They would remove rubbish, fumigate rooms, and expose to the sunshine all clothes and bedding. The sanction of the occupants would, of course, be necessary before any house was cleansed, and only men above the sweeper class should be employed.

The Pay of Civil Assistant Surgeons.

The sanction of the Government of India has been obtained to increase the pay of civil assistant surgeons appointed to be civil surgeons in Bengal. The present salary is Rs.350, rising to Rs.500. From Sept. 21st last the pay will be raised to Rs.600.

Town Planning in Madras.

Recently Professor Geddes and his sympathisers in England are not allowing the grass to grow under their feet because the *Emden* sent the Professor's preliminary collection of exhibits to the bottom of the sea. Professor Geddes tells us in an article published in the *Local Self-Government Gazette*, a newly started Madras journal, that soon after the unfortunate event an "emergency committee," including leading town-planners and architects, artists, collectors, and others interested, was spontaneously and independently formed in London and in Edinburgh, with correspondents throughout the United Kingdom, in America, and (as far as possible) upon the continent, to enable him to reorganise the exhibition; and in the interests of this committee funds are being appealed for. An exhibition, it is hoped, will be held in at least two of the three capitals of the presidencies, for even if it is upon a diminished scale it should be sufficient to afford useful illustrations of the main aspects of the movement, as it displays not only the geographical origins and conditions of cities, but also their historical development, from antiquity onwards, and the interaction of environmental and historical changes and other social factors, material and moral.

The St. John Ambulance and the French Red Cross.

The Consul-General of France in India has written conveying his grateful thanks to the Indian Council of the St. John Ambulance Association for the consignments of Red Cross gifts, valued at £240 sterling. The 12 cases containing the gifts will go by the next Messageries Maritimes steamer direct to France.

March 2nd.

SMALL-POX IN OLDHAM.—There are now 13 persons at Cinder Hill Hospital suffering from this disease.

Correspondence.

"Audi alteram partem."

LOUIS DANIEL BEAUPERTHUY AND MOSQUITO-BORNE DISEASES.

To the Editor of THE LANCET.

SIR,—“A prophet is not without honour save in his own country.” The truth of this ancient dictum is generally recognised, but it would seem that it can no longer be considered applicable in the case of the unfortunate Dr. Beauperthuy. Sir Ronald Ross in THE LANCET of March 6th takes me to task for venturing to suggest that Beauperthuy's work has at least equal merit with that of King, and he calls to his aid Dr. Seidelin, who quotes chapter and verse to show that Beauperthuy has been over-rated, that he is now, indeed, a Daniel come to judgment. It is all very interesting if not very profitable, and I think there is still something to be said for the French West Indian who, at least in his own day, had such a reputation as a physician and investigator that I understand he was specially asked by the British Government to take charge of an important leper settlement in British Guiana. This, however, is perhaps somewhat beside the mark, for here we are only concerned with Beauperthuy and his mosquito theories. After all, I did not claim very much for him. I only suggested that as Sir Ronald Ross in his interesting lecture dealt with some of the earlier pioneers, he might have mentioned Beauperthuy in the same breath as King.

Let me say at once that, like Sir Ronald Ross, my information as regards Beauperthuy was derived mainly from the writings of Sir Rubert Boyce, who quotes him freely, and from those of Dr. Agramonte. At the same time I had something more to go upon. For one thing, I had Sir Ronald Ross's own statements in his “Prevention of Malaria”; for another, I had recently travelled in some of the countries in which Beauperthuy lived and worked. Everywhere I found Beauperthuy's name held in respect and reverence. In Venezuela and Colombia alike he is regarded as having been a very great and far-seeing physician who has not received the meed of praise which was his due. Mere local celebrity, however, is not sufficient to place a man upon a pedestal, or even in a niche of the temple of fame, and so I only suggested a comparatively humble corner for Beauperthuy, one he might, perhaps, be permitted to share with King though not with Finlay and those others who paved the way for the final discoveries as regards the transmission of malaria and yellow fever.

Let us see what Sir Ronald Ross himself says. In “The Prevention of Malaria” (p. 16), when speaking of Finlay's work, which I, for one, would be the last to decry, he remarks: “Like Beauperthuy, he rightly conjectured the species of mosquito which carries yellow fever.” Again, on the next page he mentions King's able paper and says of its author: “Like Beauperthuy, he held that the insects bring the poison from the marsh and inoculate it by their bites.”

With all that Sir Ronald Ross says about the difference between the scientific speculator and the careful research worker I am in agreement, but, after all, it appears to me that Beauperthuy and King were, to all intents and purposes, in the same category, albeit it would appear that King marshalled his theories in a more logical and careful fashion. At the same time, 5 of his 19 arguments were unsound and 3 others distinctly

doubtful, as Sir Ronald Ross is careful to point out in his criticism of them. This being so, and considering that Beauperthuy was an enthusiastic microscopist in days when a microscope was a rarity in the tropics, that he wrote 30 years before King, that it is probable he tried to supplement his hypotheses by some experimental work, and that he lived in regions where, at that time, it must have been very difficult to keep in touch with scientific progress and medical literature, I do not think I was far wrong in claiming that he might be ranked with King. Let those interested consult the quotations from his writings given by Boyce on pp. 24, 25, 98 *et seq.* of “Mosquito or Man,” judge for themselves.

I can follow the arguments advanced by Sir Ronald Ross, but I confess that some of Dr. Seidelin's present difficulties. In the first place, I should say that Beauperthuy's idea that most infectious diseases are spread by ascaridæ (elsewhere he speaks of “acariens”) or “insects” might well be accounted to him for righteousness, considering his day and generation and what we now know as regards plague, typhus, and many other communicable disorders. Again, Dr. Seidelin might take into account the difference between a starving and a gorged stegomyia. While I admit the former could rarely, if ever, be described as “silly” or “dull,” the latter is often in such a condition that it makes no attempt [to evade the avenging hand or flapper. It is at least possible that Beauperthuy was thinking of the gorged and sluggish insect.

Yet again, when discussing the views of Agramonte, Boyce, and Guiteras, Dr. Seidelin, on the whole, tends to support the last named. Now Guiteras, as Dr. Seidelin shows, takes Beauperthuy's “zancudo bobo” to be *Culex sollicitans*. Dr. Seidelin also thinks that Guiteras is correct in translating Beauperthuy's statement in such a way as to make the latter state that *Culex sollicitans* is not concerned with the spread of yellow fever and malaria. If this is what Beauperthuy meant, then Beauperthuy, so far as we know at present, was quite correct. It is certainly a curious way to belittle a man by showing that he was right, even though his correctness consisted in making a negative assertion. In this connexion surely Dr. Seidelin meant to quote Guiteras as saying “harmless,” not “harmful”; otherwise his argument is still more involved.

I have written at some length, for my recent visit to the West Indies and South America stimulated my interest in Beauperthuy and his prophecies. At the same time, had it not been for the war there would have been no need for me to undertake the defence of my very mild suggestion. My friend Dr. Paez, of Ciudad Bolivar, tells me that Professor Blanchard, of Paris, had prepared a special paper on Beauperthuy and his work for the *Archives de Parasitologie*. It would have seen the light ere now but for the outbreak of hostilities. I am sensible of the fact that the knowledge of the subject which I possess is not sufficient to enable me to class Beauperthuy beyond giving him an equal place with King in the Valhalla of the mosquito theorists. Hence I am content to leave the former and his claims to recognition in the hands of his distinguished countryman, although, thanks to the kindness of Dr. Paez, I hope soon to read Beauperthuy in the original and to find out how his “zancudo bobo” strikes me, and whether I agree with Guiteras or Agramonte.

I am, Sir, yours faithfully,

ANDREW BALFOUR.

Wellcome Bureau of Scientific Research, Henrietta-street, Cavendish-square, W., March 18th, 1915.

FOREIGN SERVICE AND THE AGE LIMIT.

To the Editor of THE LANCET.

SIR,—Sir Alfred Keogh in his letter in your issue of March 13th (p. 572) makes a stipulation in paragraph 4 which must limit considerably the numbers at his disposal. He says that except in special cases men of over 40 years of age are not sent overseas. It seems that no distinction is made between two entirely different branches of the medical service in France. On the one hand, there is the work actually at the front, on the lines of communication, &c.; and on the other, the work at the base hospitals. Perhaps for the former, where severe conditions are inevitable, an age limit of 40 is desirable, but for work at the base hospitals surely the services of men of experience, even though past the magic age, are not only welcome but indispensable. If a strict age limit is made it will necessarily follow that the base hospitals will be staffed by young, inexperienced men, who, as compared with the civil hospital standard, are not surgeons at all, and yet they must decide questions and perform operations that require years of training. My own experience of this campaign in France assures me that the work of a surgeon at the base hospitals is not nearly as trying as the daily work of an operating surgeon at home, and could easily be done by men between 40 and 60, an age when experience and matured judgment are at their best. If this suggestion of supplying older men in the base hospitals could be adopted it would release a large number of younger men, who would, I know, jump at the chance of getting right to the front.

I am, Sir, yours faithfully,

Harley-street, W., March 16th, 1915.

H. W. CARSON.

TREATMENT OF PAINFUL FROST-BITE.

To the Editor of THE LANCET.

SIR,—The problem of how best to treat painful frost-bitten feet is one which doubtless has caused those in charge of military wards some anxiety.

The best remedy I have found to be the following:—

R. Cocainæ...	...	...	gr. viii.
Ol. olivæ...	...	...	3 iv.
Liq. calcis	...	...	3 iv.

Which simply means carron oil and cocaine. A small quantity is rubbed into the feet twice daily, special attention being given to the toes. The feet are massaged with it for a few minutes, afterwards being wrapped up in cotton-wool. It is an improvement to add 1 ounce of liquid paraffin to 4 ounces of carron oil. By this addition it prevents it oxidising so quickly and also from drying up so rapidly, and makes it less liable to rancidity. When the oil dries on the feet the following dusted on is an excellent powder: camphor, gr. xxxv.; zinc oxide and pulv. amyli, aa 3 ss.

In all my recent cases in which there has been no ulceration it has been entirely successful; one advantage of this form of treatment is that the patient is able to sleep without any narcotic. When the acute stage passes off, the carron oil and cocaine are mixed with equal parts of carbolic oil, the percentage of which is increased as the pain decreases. Another very important consideration is the fact that the men can be the more quickly put on the convalescent list, thereby enabling them to get back sooner to the front.

I am, Sir, yours faithfully,

W. CHARLES DAVIS.

David Lewis Northern Hospital, Liverpool, March 19th, 1915.

THE ANCESTRY OF EHRLICH.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 27th (p. 422) Sir W. Watson Cheyne is reported as saying, "Whatever may be thought of German Kultur in general Professor Ehrlich is the great pioneer in this work [chemotherapy]. . . . I look upon Professor Ehrlich as the greatest medical asset that the world possesses at the present time."

Now, I hope you will pardon me for pointing out that although possibly a *naturalised* German, Professor Ehrlich is stated by Dr. Garrison in his "History of Medicine," p. 95, as springing from a more ancient and more famous race—viz., the Hebrews—and Dr. Garrison also cites Cohnheim, Metchnikoff, Fränkel, Friedländer, and Neisser as belonging to the same ancestry. As Disraeli says in "Lothair," "Race is everything."

I am, Sir, yours faithfully,

Corris, Merioneth, March 19th, 1915.

E. C. B. IBOTSON.

A PLEA FOR CONSIDERATION.

To the Editor of THE LANCET.

SIR,—Your leading article with this title prompts me to write this letter, though I have not the honour to belong to the profession by which you are almost exclusively addressed.

When the Insurance Act began to increase the emoluments of practice for some practitioners who joined the panels the cry that "the doctors" were getting overpaid was raised in many quarters by persons who equally would have been opposed to the raising of the salaries offered for those posts which are now so difficult to fill. To those who think that the medical profession has been, or is ever likely to be an overpaid calling, I may commend the careful consideration of the work now being done by it on and in connexion with military service, the demand for more men to do that work, and the shortage of medical men in civil practice.

The proposition is that if the practice of medicine had offered better prospects of livelihood to the able young men who have had to choose callings for themselves during the past 30 years, there would have been a proportionately larger supply to draw upon in this great crisis of our national life. Grudgingly paid fees of the smallest possible dimensions, and salaries fixed at the lowest price to which competition can reduce them, have imposed upon many the necessity for arduous work by night and day before the bare necessities of life are earned, and have combined, under the inexorable law of supply and demand, to keep down the numbers of the medical profession in time of peace. In time of war it is too late to add to those numbers, because the training of the physician or surgeon is a matter of years not of months, and the numerical insufficiency now realised can only be made up for by strenuous devotion to duty, on the one hand, combined with reasonable patience and forbearance on the part of the public.

Neither devotion to duty nor patience will be relaxed at a time when our country with every resource at its command is fighting for the preservation of its national existence; but thoughtful citizens might well consider, when the war is over, whether a shortage of medical men is a safe national position. And if they find that it has its risks then will be the time to take the obvious measures of precaution.

I am, Sir, yours faithfully,

March 22nd, 1915.

A LAWYER.

Obituary.

WILLIAM MURRAY DOBIE, M.D. EDIN.,
M.R.C.S. ENG.

Dr. William Murray Dobie, of Chester, who died, aged 86, on March 12th, was the son of Dr. W. Johnson Dobie, of Graysford. He was born in Liverpool and received his medical education at Edinburgh, graduating M.D. at the University in that city in 1849 with the gold medal in surgery. He became M.R.C.S. Eng. in 1854. At the Edinburgh Royal Infirmary he held various residential appointments and had the advantage of studying under Syme, forming lasting friendships with Lister and Murchison. After visiting Paris, Berlin, and Dublin he commenced practice in Chester in 1855, in which year he married Janet, daughter of Mr. William Smith, of Rossett, by whom he had five daughters and five sons. Three of the sons are now medical practitioners in Chester. During the cholera epidemic in 1867 Dr. Dobie rendered great service in checking the ravages of the disease, and in connexion with this subject wrote an article on chlorine in the treatment of Asiatic cholera and choleraic diarrhoea for the *Edinburgh Medical Journal*. In 1875 he was elected honorary physician to the Chester Infirmary, and on his resignation in 1895 was made consulting physician. He was also honorary consulting physician to the Wrexham Infirmary and to the Royal Alexandra Hospital, Rhyl. From 1893 to 1895 he was President of the Chester Society of Natural Science and Literature.

In 1896 Dr. Dobie was publicly presented with his portrait in oils, painted by Mr. W. W. Oules. The then Duke of Westminster, who was supported by all the leading inhabitants of Chester and district, made the presentation. He received the freedom of the city of Chester, of which he was a magistrate, in 1897. He was much attracted by microscopical and astronomical studies, and among his early contributions to science were the discovery and description of a new crater in the moon which bears his name. Dr. Dobie, it will be remembered, attended Gladstone in his last illness.

WILLIAM GILBERT DICKINSON, M.D. DURH.,
L.R.C.P. LOND., D.P.H. ENG., M.R.C.S. ENG.

A STRENUOUS life reached its termination on March 19th, at Clifton, Bristol, where Dr. William Gilbert Dickinson had been living for a year or so since he retired from practice at Portishead. He received his medical education at St. Thomas's Hospital, and from 1875, when he obtained the Diploma of M.R.C.S. Eng., took great interest in the administration of the affairs of his College. He belonged to the Association of Members founded in 1884, and was largely instrumental in founding the Society of Members, for whom he acted as honorary secretary for 15 years, only resigning in 1909, when he left Putney for a less exacting practice at Portishead. For this long period he was one of the leaders in the demand for reform in the Royal College of Surgeons of England, but he was ever a courteous controversialist. Any and every movement for the advantage of his fellow practitioners met with his hearty support. He was therefore to be found concerned in the management of the Medical Sickness Society and of the London and Counties Medical Protection Society. He was the author of many papers on the better organisation of the medical profession.

DAVID MOORE ALEXANDER, M.D. LIVERP.

Dr. David Moore Alexander, who died on March 18th at the early age of 37, after having been ill for only a few days with pneumonia, was the only son of Dr. William Alexander, consulting surgeon to the Royal Southern Hospital, and was educated at Liverpool College and at the University of Liverpool. After graduation he studied at the Pasteur Institute in Paris. He was subsequently appointed assistant lecturer in bacteriology at the University and bacteriologist to the Liverpool corporation. He carried out several researches for the Local Government Board, the most important being in connexion with the bacteriology of infantile diarrhoea. He was secretary to the pathological meetings of the Liverpool Medical Institution, and he had just obtained a temporary commission in the Royal Army Medical Corps, and was proceeding to the front with the Liverpool Mobile Hospital as its bacteriologist. The loss of his scientific attainments to the city and the University is a great one, and by numerous friends he will be missed sorely.

THOMAS RAWDON GLYNN, M.B., B.C. CANTAB.

THE death occurred on March 9th of Dr. Thomas Rawdon Glynn at the early age of 35 years. He was the second son of Dr. T. Robinson Glynn, professor of medicine in the University of Liverpool, and brother of Dr. Ernest E. Glynn, the professor of pathology there. He was educated at Liverpool College and the University of Cambridge. After graduating in medicine in 1910 he held the usual resident appointments at the Liverpool Royal Infirmary, and later was elected physician to the Hospital for Consumption and Diseases of the Chest, Liverpool. Some years ago he discovered that he was suffering from a malady which would in all probability put a term to his existence in a few years. He determined, however, that he would not allow this knowledge to interfere with his professional aims and usefulness, and while not neglecting rational precautions to preserve his health he gladly undertook whatever work came to his hand. He continued at work until a few weeks ago, when he went to stay at his father's country house, Nerquis Hall, Flintshire, where he passed peacefully away. He is mourned by many friends, and his persistence in work almost up to the last without any complaining—in fact, few but his relatives knew of his illness—was a fine example of courage.

ERRATUM.—The age of Sir George Turner was wrongly stated in our obituary notice last week. A personal friend of his points out that Sir George Turner was born on Feb. 10th, 1848. He was therefore in his 68th year at the time of his death.

TUBERCULOSIS DISPENSARY FOR TORQUAY.—

At the last meeting of the Devon County Council it was reported that a provisional arrangement had been come to for settling the action which had been commenced with a view to restraining the county council from using the residence, "Larchmont," Torquay, as a dispensary for tuberculosis. The council has decided to reimburse the legal costs of the owners of the property, which amount to about £117, and to erect a boundary wall on both sides of the premises. As already mentioned in THE LANCET, there has been much local opposition to the scheme, so that the agreement is regarded as a satisfactory termination of a very troublesome matter.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE demands on the Fund made by the needs of refugee doctors and pharmacists and their families and dependants have been a little heavier of late, one reason being that the need for clothes is growing with the length of exile.

It has been possible to find occupation for a certain number of Belgian doctors in British civilian practice, when the Fund has defrayed the expenses of registration; but the total of refugee doctors has been decreased by the absorption of a certain number of them into the Belgian army, where it is understood there is still need of men to take medico-military commissions. Those Belgian medical men whose age, health, or private engagements prevent them from serving their cause in this way would find it much easier to obtain posts in this country if they could speak a little English, and some surprise has been expressed that so few of them have as yet taken advantage of the facilities which have been offered in this direction.

The week's subscriptions include additions to many lists that have been open for some time, and in certain cases the aggregate of the donations up to date is published.

MANCHESTER AND DISTRICT.

Dr. E. Brockbank announces that £473 6s. 6d. had been received from medical men and the general public in Manchester and the district up to March 21st, and £10 4s. 11d. from the pharmacists. This local list will now close, and Dr. Brockbank, the secretary (Northern Assurance Buildings, Albert-square, Manchester), will be glad to receive any subscriptions immediately, and to hear if any of the contributions have not been acknowledged in the journals. The following additional subscriptions have been received:—

£ s. d.	£ s. d.
Dr. J. B. Dalton, Dr.	Mr. H. L. Whitestone ... 1 1 0
A. E. Finney, Mr. J.	Dr. G. R. Gordon ... 1 1 0
Gilmour, Mr. J. H.	Mr. W. P. Lynn ... 1 1 0
Hacking, and Mr. J. N.	Dr. J. H. Godson ... 1 1 0
Platt ... 4 4 0	Dr. C. Hawkins Craig ... 1 1 0
Dr. W. White ... 2 2 0	Dr. H. Mackenzie ... 1 1 0
Dr. P. L. Pearce ... 1 1 0	Dr. F. C. Scotson ... 1 1 0
Dr. O. H. Woodcock ... 1 1 0	C. N. ... 0 7 0

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, and not including money collected by certain local funds, and the Scottish and Irish Funds, are as follows:—

£ s. d.	£ s. d.
Shropshire and Mid-Wales Branch, B. M. A. (sixth donation, total £452s. 6d.)	£124 12s. 6d. (per Dr. Major Greenwood, Hon. Treas.) ... 2 0 0
Dr. L. E. Dickson ... 0 10 6	South-West Wales Division, B. M. A. (per Dr. D. R. Price, Hon. Sec.)—
"J. M." ... 25 0 0	Anon. ... 0 10 0
Dr. Wm. B. Jack ... 1 1 0	Norwich Division, B. M. A. (third donation, total £51 3s.) (per Dr. G. P. C. Claridge, Hon. Sec.)—

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd. £8250 had passed into the treasurer's hands by Tuesday last, the sum not including the Scottish and Irish and several large local funds.

Last week an acknowledgment in the subscription list as follows: Messrs. Benger, Ltd., £26 5s. 0d., should read, Messrs. Benger's Food, Ltd., £26 5s. 0d. Mr. and Mrs. Dinphie, £5, should read, Mr. and Mrs. Dunphie, £5.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments kindly contributed by the following gentlemen since the publication of the last list:—

Dr. Ick Hewins, Tokomaru Bay, New Zealand; Dr. C. E. Hardyman, Bramerton, Norwich; Dr. James Hudson, Newcastle-on-Tyne; and the Library of the Manchester Medical Society (per Dr. Brockbank).

DONATIONS AND BEQUESTS.—The late Miss E. Addiscott, of Clifton, has bequeathed £1000 each to the Bristol Children's Hospital, the Bristol Dispensary, and the Bristol Medical Mission.—Under the will of the late Mr. William Edgar Allen, of Sheffield, the Hospital for Consumption at Ventnor will receive £1000 and the Mission to Lepers in India will benefit by a similar amount. The University of Sheffield benefits largely under the will, £5000 being placed at the disposal of the applied science department, besides bequests for the founding of scholarships and exhibitions.—By the will of the late Sir J. Donaldson a fund, to be called the Lady Donaldson Fund, will be established in the St. Andrews University for aiding students attacked by illness or labouring under disease during attendance at the University.—The following legacies have been left under the will of the late Mr. Charles Vivian, of Bedford: £5050 to the Middlesex Hospital, £4000 each to the London Hospital for general purposes and Dr. Barnardo's Homes, £3000 to the Bedford County Hospital, and £2000 to the Cancer Hospital, Brompton.

The War.

THE CASUALTY LIST.

THE casualties among officers in the Expeditionary Force reported since our last issue include the names of the following medical officers:—Killed: Lieutenant W. T. McCurry, R.A.M.C., and Lieutenant J. R. Waddy, R.A.M.C. Died of wounds: Lieutenant D. C. Turnbull, R.A.M.C. Wounded: Captain F. O'D. Fawcett, I.M.S., Captain J. Taylor, I.M.S., Lieutenant F. C. Davidson, R.A.M.C., and Lieutenant A. G. Biggam, R.A.M.C.

THE INCREASED PREPARATIONS FOR THE WOUNDED.

Clearly, before many months, or perhaps weeks, have passed the accommodation for the sick and wounded from the front will have to be considerably increased, and in addition to the provision made at general hospitals other institutions all over the country for this purpose are being requisitioned by the War Office. Although the demand for sick and wounded accommodation will be great, we have every confidence that the need will be adequately met. But the proper housing of the sick and wounded is only one of the problems: there remains the question of nursing. For many cases any woman possessed of the nursing temperament may, with a short training, become an efficient nurse to work under the supervision of a fully-trained chief, and a suggestion by Lord Knutsford that the best way of meeting the increased demand for nurses would be for hospitals to take probationers and begin their training at once deserves earnest consideration. The London Hospital, he says, has already taken 70 short-time probationers who "will be of infinite use to work under trained supervision in any of the new hospitals which are to be opened." This will be only extending the condition of things which normally prevails, inasmuch as probationers in our large hospitals are always working under trained nurses. Those who have already received some training under the Voluntary Aid schemes and under the Red Cross, as well as private first-aid students, should make valuable nurses with a short hospital training; and if they were content to confine their services to this country and not aspire to work abroad, where trained supervision is not so easy to provide, much good might result. It is not expected that such nurses should continue in this vocation after the war, but the knowledge which they would have gained would be of incalculable value in their own homes, and perhaps prove an efficient aid in promoting the health and well-being of the country. Among minor problems, a larger use of partially trained nurses obviously necessitates a better classification of the wounded as they are drafted into the various institutions; also there is the question of housing the nurses themselves. But the whole question, or rather series of questions, we doubt not will be easily solved in the course of events by the common-sense of the authorities, combined with the benevolence and goodwill of the community generally.

THE ITALIAN MEDICAL SERVICE.

An important discussion took place in the Italian Senate on March 13th upon this subject. The Minister Zupelli stated that the civilian members of the profession would be called upon; that they would be given temporary rank of lieutenant or

captain up to 36 years of age, and higher ranks in the base hospitals beyond the fighting line; that university clinics with all their personnel would, wherever possible, be mobilised *en bloc* for the reserve hospitals, and that the personnel and material of the Croce Rossa would be placed under the command of the Army Medical Department. The Army Medical Staff consists at present of 800 officers on the active list, 1800 on the auxiliary list, and 1800 between the Territorial and reserve establishments. This means, as Senator Maragliano pointed out, a shortage of some thousands of medical officers in the case of a European war. Senator Zupelli alluded to the outbreak of cerebro-spinal fever in certain garrisons, but declared that there had been no fresh cases for some days. There had been 350 cases in all, with 140 deaths. Antityphoid inoculation has been made compulsory; it is expected that all the troops will have been inoculated by the middle of April. Provision is making for the adequate supply of antitetanic serum and anticholera vaccine. A number of the universities are holding courses in military surgery and hygiene for practitioners and senior students.

THE SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE AND MEDICAL OVERPRESSURE.

This committee has issued the following memorandum. The Director-General of the Army Medical Service, in his public letter of March 10th, makes the following statement: "The need for medical men both for home and foreign service is acute. We want every qualified man who is physically fit and willing to serve." This statement must convince everyone of the seriousness of the problem of medical supply, civil as well as military. As a contribution to its solution the Emergency Committee, in the interest of the nation, desire to make through the press the following appeals:—

1. *To the public.*—It will materially help to relieve the great strain now imposed upon the medical practitioners remaining at their posts throughout the country, many of whom are at present working 15 to 16 hours a day, if patients and their friends will make a point of sending messages for the doctor as early as possible in the morning, so that the doctor may arrange his daily round in the way most economical of time. In many parts of the country this practice has already been partially adopted. We ask everyone to give effect to the suggestion. Where the case is not an urgent one, and a visit on the next day would suffice, this fact should always be stated in the message.

2. *To the local educational authorities.*—Regular medical inspection of school children is very important, but it is not nearly so urgent as attendance on patients who are dangerously ill. These have clearly the first claim for medical care. We appeal to school boards and other educational authorities to release entirely, or in part, those of their medical officers who are willing during this emergency to resume general medical work for the public. We have reason to anticipate that this proposal will not be received unsympathetically by the Scotch Education Department.

3. *To retired doctors of the profession who are still* (in Sir Alfred Keogh's words) "*physically fit and willing.*"—The Emergency Committee will be happy to hear from these, and will endeavour to give them opportunities for service in circumstances that will not involve an excessive strain.

4. *To the younger lecturers and assistants in the medical schools.*—At this time of the year, when the winter session closes, the teachers usually go for a week or ten days' well-earned holiday. We ask them this year to substitute a change of work for the customary holiday, and to offer their help to country colleagues in difficulty. Many practitioners, especially in rural districts, have been overworked for months, and some of them are breaking down under the strain. The temporary help of a professional brother from the schools

would ease this strain, while the stimulus of his timely coöperation would act as a useful tonic for the trying days that are still to come.

The Emergency Committee is confident that their action in making these appeals will not be misunderstood. The times require the mobilisation of all our professional forces. All are desirous to help if they knew how. The function of the Emergency Committee is to indicate how and where help may be most effectively afforded. Communications should be addressed to the Convener, Emergency Committee, Royal College of Physicians, Edinburgh.

THE ENGLISH HOSPITALS UNDER FRENCH MILITARY AUTHORITY.

Three hospitals, which come under the heading implied by this title, were founded in France, of which two, one at Nevers and one at Limoges, continue their work. The third, the hospital at the Hotel Majestic in Paris, was closed some weeks ago. The hospitals are largely staffed through the Union des Femmes de France, one of the three branches of the Croix Rouge Française, to which body the defunct Hotel Majestic hospital definitely belonged. The hospitals at Limoges and Nevers, ranking as French military hospitals under the chief French medical officer of the XIIth Army Region for Limoges and of the VIIIth Army Region for Nevers, are subject to inspection by the French military medical authorities, and have French officials attached to them. We are indebted to Dr. Haden Guest for notes as to both hospitals during the period of their activities, signed by their principal medical officers.

Hôpital Militaire Anglais, Limoges.—This hospital, installed in the School of Art of the Musée Debouche, Limoges, was opened on Oct. 10th, 1914, with accommodation for 150 patients nominally, although frequently it has accommodated 160 and more. It is a four-storeyed building, each floor of which is divided into three main halls with smaller rooms at each end of the ground, first, and second floors; annexed to the ground floor is a glass structure which has been utilised as a receiving ward. The smaller rooms at each end of the ground floor are used as the bureau of the médecin-en-chef and the housekeeper's room respectively, while the front hall has been converted by the erection of wooden partitions into dispensary, linen-room, clerk's office, and storeroom. The second hall is the dining and recreation room for the medical staff, and the third hall is the mess-room for the French employees of the hospital. On the first floor the smaller rooms are used as operating theatre and matron's room respectively, and the larger *salles* are used as wards; a similar arrangement holds good on the second floor, except that the small rooms are used as X ray room and house surgeon's room. The whole of the top floor is taken up by nurses' dormitories. The kitchen is detached from the hospital, and outbuildings have been utilised as mortuary and storeroom for the kits of wounded soldiers. Along the front of the first and second storeys run two long corridors, at either end of which are lavatories for the use of patients and staff. The building has been admirably adapted for the purpose of a hospital; while Limoges itself is on the main line from Paris to Bordeaux, 400 kilometres from Paris.

When the hospital was first opened considerable difficulty was experienced in transporting patients from the firing line to Limoges, but men are now brought in direct from the front within 30 to 40 hours. The local expenses of running the hospital amount to about 600 francs, or £24 a day, about half of which is provided by the French Government for the maintenance of patients; to this must be added the administration expenses incurred in Paris and London. More than half of the total local expenses consist of the cost of provisions. Since the local expenses for December were about 20,000 francs, January 19,000 francs,

and February 16,000 francs, it will be seen that a vast amount of good work is being done at a minimum of expense. The working expenses have been reduced to the lowest possible figure compatible with the highest state of efficiency, and I think this hospital reflects, and will continue to reflect, much credit on the Wounded Allies Relief Committee. The following figures give the work of the hospital:—Patients treated in hospital since the opening, Oct. 10th, 1914, to Feb. 28th, 1915, number 397, of whom 247 have been discharged, 142 are still in hospital, and 8 have died. Of the total number treated in hospital, 4 were British (all discharged), 12 were African natives, and 381 were French. Of the 247 discharged from hospital, 18 were finally discharged from the army (active service), amputated or trephined; 49 were discharged to duty after 8 days' furlough; and 180 were discharged with 1 to 2 months' furlough. The number of discharges per month were: October, 4; November, 52; December, 82; January, 67; and February, 42.

Hôpital Militaire Anglais, Nevers.—Lieutenant-Colonel Charles Boyce, R.A.M.C., médecin-en-chef, writes of one month's work as follows:—"I arrived in Nevers on Jan. 24th. On the previous day a large convoy of wounded and sick numbering 79 cases were received. This number exceeded the bed accommodation by 14. There was apparently some misunderstanding, and the railway military staff, who distribute the wounded to the various hospitals, sent more cases than were asked for. Some spare beds were found, and on these and mattresses put on the floors the extra number were placed and the difficulty overcome. A considerable number of the wounded, many of whom came from the trenches in the Argonne, were suffering from very severe wounds. Their wounds were mostly resulting from high-explosive shells and shrapnel, and of these three died during the month. One was moribund on admission and died from gas gangrene, the second was due to pyæmia occurring after amputation for gangrene, and the third was wounded by a ball in the pelvis. The projectile could not be found; abscesses formed, with purulent absorption, exhaustion, and death. All the cases suffering from wounds were septic. Among those who arrived on Feb. 15th were two cases of men who had suffered merely from abrasion of the skin over the knee, but each of these was septic and with high fever. The wounded had passed, in many cases, several days between the receipt of their wounds and admission here, and only one dressing had been applied on arrival here; the dressings were soaked with discharges and very offensive.

The arrangements for the removal of the wounded from the train are excellent; the siding from the railway station at Nevers, by means of which the trains convey the wounded to the hospital, is most convenient and saves the patients much extra fatigue. On the occasion of the arrival of the wounded on Feb. 15th all the patients were transported to the hospital, their clothing taken off, they were put in bed, and were supplied with hot beef-tea in two hours—a very fine performance, which shows how well the nurses and orderlies worked. On this occasion we had 36 patients, many of whom were very severely wounded. Fresh dressings were applied to all cases requiring them, pieces of shrapnel lying superficial were removed or urgent operation was performed as soon as possible after admission, and on this occasion everyone was not attended to until 2.30 A.M. We have had a considerable number of medical cases, the greatest being in the convoy which arrived on Jan. 23rd. Amongst these were 6 cases of typhoid fever, one of whom also suffered from a fractured patella (he is now convalescent from both); 3 cases of pneumonia; several of bronchitis and lumbago, the latter the result of standing for long hours in cold water. Several cases were sent of such a trifling nature that they ought to have been forwarded to a convalescent hospital and not here.

On Jan. 24th there were 114 patients in the hospital. Between Jan. 24th and Feb. 24th 64 patients were discharged and 49 new cases admitted. Of the latter, 36 came in one convoy by train; the remainder, 13 in number, were admitted from other hospitals in Nevers. The military authorities asked us to take them in, either for operation or to relieve pressure on their hospitals. On Feb. 25th I discharged 6 cases and admitted by special request from the médecin-chefs of two hospitals, 3 cases of appendicitis and 3 men with projectiles on their bodies for X ray and operation. The first wounded arrived on Dec. 6th,

1914, and from that date until Feb. 24th, 1915, 108 operations were performed. Between Jan. 24th and Feb. 24th, the month under review, 52 were performed. These were distributed on the various floors of the hospital as follows:—

Total.	From Jan. 24th to Feb. 24th.
A. 35	A. 19
B. 43	B. 23
C. 30	C. 10
108	52

The number of patients treated at the hospital since its opening has been 239; of these 148 have been discharged and 4 have died."

THE EFFICIENCY OF THE GERMAN ARMY MEDICAL SERVICE.

A Swiss correspondent writes:—A party of Swiss and Italian doctors, all connected with the Red Cross Societies of their respective countries, have just returned from a prolonged visit to Germany and the Western battle-front, and they visited Berlin, Sedan, Saint Quentin, Brussels, and the town—naturally not named—where the German General Staff has its present headquarters. They were received everywhere with the greatest courtesy, and they express their delight at their visit and their admiration for the German Army Medical Service, and the impressions recorded by one of the party, Professor Baldo Rossi, are probably shared by the others. He says:

The organisation of the German medical service is simply wonderful. Nothing seems to have been left to chance, but, on the contrary, every detail seems to have been thought out carefully. At Berlin a large number of public and private buildings—theatres, cinematograph houses, police stations—have been handed over to the Army Medical Department, while various types of hospitals are situated at different points along the main roads which link up the capital to the fighting line. The wounded are not removed from the trenches until evening, as there is the danger of transports being attacked in the daytime by the enemy. Medical assistance is, of course, rendered immediately, and the German trenches, moreover, are not uncomfortable places. At dusk ambulances drawn by horses reach the trenches and the wounded are transferred into them. Horse ambulances are used because the roads are frequently too difficult for automobiles, and because, even were the latter used, the noise of the motors and the glare of the headlights would attract the enemy. The wounded are first taken to the medical stations situated about five miles in the rear of the trenches, each of which is under the supervision of nine doctors, of whom three are surgeons and one an oculist. These medical stations have been carefully selected and contain operating tables, instruments of the most expensive and intricate kind, and all drugs that might be required. Many of the beds in use are curious, and offer testimony to the practical nature of the Germans. The number of wounded proved so much greater than had been anticipated that the ambulance men were compelled to make beds to the number of many thousands from the boxes and cases which had contained food for the troops.

Of the usual nature of the wounds of the German soldiers Professor Rossi says:—

Most of them are caused by cannon projectiles, whereas in preceding wars injuries were mainly due to rifle fire. Wounds in the head are numerous owing to the trench fighting, which is the chief characteristic of the campaign. Instances of "frozen feet" are not frequent, one reason being that the German soldiers wear very high boots. Amputation, practised so largely in previous wars, is now reserved by the Germans for desperate cases, so that at the end of the present war, vast and terrible though it is, mutilated men will not be very numerous.

At Brussels the party attended a conference of German medical men who discussed Belgian health problems.

HOW TO APPLY FOR A TEMPORARY COMMISSION IN THE R.A.M.C.

In reference to the appeal by Sir Alfred Keogh, published in THE LANCET of March 13th, there have been many complaints as to the difficulties of those unacquainted with official routine in taking the initial steps. If the candidate lives out of town he should apply by letter to the Secretary, War Office, Whitehall, S.W., when forms of application and conditions of service will be sent to him. It is not necessary to enclose a stamp. For those who live in London the process is simplicity itself and is graphically described by a correspondent in the *Times* of March 20th as follows:—

Go to an entrance of the War Office in Whitehall marked Enquiry Office. The policeman will direct him to a room, where he fills in a form stating the nature of his business; a clerk takes it, stamps it, and passes it on to another clerk who calls out applicant's name, gives the form to a boy messenger, and tells applicant to follow the boy. The applicant is taken to the office concerned; a courteous official hands the applicant two forms, one stating the conditions of service, the other a series of questions inquiring what are his qualifications, his age, his nationality, whether he has held any Government appointments, &c. This form he can fill in there and then or take it home and consider. The whole process did not take more than 20 minutes.

The writer in the *Times* deals, however, only with the process for obtaining the form of application. The form, when it arrives, is not explicit or very informative.

WAR PREPARATIONS IN MANCHESTER.—The military authorities have commandeered seven of the largest and most modern municipal schools in Manchester. This will necessitate other provision for the accommodation of the 8000 dispossessed school children. These seven schools will accommodate 1015 wounded soldiers; in addition, one house in Stretford will accommodate 90 beds. In Salford five schools will be taken over by the military authorities. These preparations will entail a big demand on the nursing resources of the city, for considerably over 200 trained nurses will be required. Already nearly 100 trained nurses and probationers have been enrolled to begin work this week. Since October last 50 young women have been voluntarily rendering service in various military hospitals. Many beds are occupied by wounded soldiers in the Royal Infirmary. In Salford Royal Hospital there are 145 wounded soldiers, others are in Ancoats Hospital, the Eye Hospital in the city, and the military authorities are making inquiries as to the provision of further hospital accommodation for sick and wounded soldiers at Crumpsall Infirmary, where the authorities have resolved to place every facility in the hands of the War Office. The accommodation could possibly be extended from 250 to 600 cases. A further trouble will be to obtain the additional medical assistance and additional nurses required for the 600 soldiers who may eventually be taken at Crumpsall. Of course, all this is in addition to the beds already available in the Western Base Hospital and hospitals in towns around Manchester.

PROMPT CARE OF THE WOUNDED.—The testimony to the efficiency of the work of the R.A.M.C. is almost universal, but a concrete instance may perhaps help to bring it home more in detail. A lay contemporary relates that a soldier was wounded at Neuve Chapelle at 2.30 A.M. on March 13th on his way to the trenches. A shell exploded almost in his face and he was struck in the head. He lay an hour where he fell with "shrapnel flying over him all the time," picked himself up, and was assisted to the field dressing station at 3.45 A.M., whence he was taken by motor-ambulance to Estaires Hospital, arriving there at 8 A.M. After being attended to he went in another motor-ambulance to the hospital at Merville, leaving in a hospital train at 7 P.M., and arriving at Boulogne at 9 P.M. He was taken in the hospital boat at once, was asleep when it sailed, and arrived at Southampton next day at 2 P.M., London at 7 P.M., Waterloo at 9 P.M., and in his bed at the London Hospital at midnight, 45½ hours after he was wounded.

MORE WOUNDED SOLDIERS FOR DUBLIN.—A French hospital ship arrived in the Liffey from Boulogne on Friday, March 19th, carrying 390 wounded or sick soldiers. Five deaths had occurred on the voyage. The disembarkation of the soldiers was carried out with great expedition, the R.A.M.C. receiving useful help from the St. John Ambulance Brigade. Nearly all the wounded were "stretcher cases." Of the total number about 150 were brought to Dublin Castle, the remainder being distributed among the several city hospitals. Most of the men were wounded in the recent fighting near Neuve Chapelle, and their condition is more serious than that of any previous detachment of wounded which has arrived in Dublin.

SOLDIERS' AND SAILORS' HOSTELS.—We should like to see all the big railway companies at their termini in London, Liverpool, and other large cities following the lead set by the Great Eastern Railway, which has opened a soldiers' and sailors' hostel close to Liverpool Street Station. Sleeping accommodation is provided for about 50 and provision is made for washing, drying clothes, getting hot coffee, &c., for men on service who arrive early in the morning, or have some time to wait. While a small charge is usually made to those who can pay it, the conveniences are not forbidden to those who cannot.

THE UNIVERSITIES AND WAR.—Dr. Alexander Hill, Principal of University College, Southampton, at the prize distribution there on March 22nd, stated, on the basis of an investigation made by him, that the Universities and University Colleges of the British Empire contributed over 50 per cent. of the men on military or naval service. The German Universities, on the other hand, contributed less than 20 per cent.

THE "HOSPITAL OF FRIENDSHIP."—This is the name given by Lady Bagot to the first movable hospital in Belgium, organised by her a few weeks ago in response to the urgent appeal of Inspector-General Melis, the head of the military hospitals in Belgium, with the Belgian Minister as president and Lord Charles Beresford as chairman of committee. It is now serving within a short distance of the Belgian firing line, where it serves as a half-way house between the field and the base hospital. It is constructed of wooden panels assembled by iron bolts and screws, and can be taken down and packed within 12 hours and moved on by motor lorries. The ward of 24 beds is 70 feet long, with an operating-room, kitchen, store-room, &c. The staff consists of ten doctors chosen by the Order of St. John of Jerusalem, with dressers and orderlies. The cost of maintenance amounts to a little over £50 a week. The work of the hospital is highly appreciated by our Belgian friends, and quite justifies its title. Funds are desired to enable a second ward to be opened. A guarantee of £1000 would render this practicable and maintain its 24 beds for three months. The treasurer is Mrs. Robert Crawshaw, 75, Upper Berkeley-street, Portman-square, and the bankers Messrs. Child and Co.

A FIELD BACTERIOLOGICAL LABORATORY.—A movable bacteriological laboratory on wheels has been presented through the Chancellor of the Exchequer to the Welsh Army Corps by Mrs. Lynn Thomas. The laboratory is well equipped, and is adequately ventilated and lighted, and its staff comprises a surgeon, an orderly trained to bacteriology, and a driver.

THE EDUCATION OF OFFICERS' SONS.—The council of the Imperial Service College appeal for money to enable them to educate the sons and descendants of the many officers of the army and navy who have been or shall be killed in the war leaving their families in straitened circumstances. The appeal is supported by Lord Kitchener, Sir John Jellicoe, and Sir John French, and cheques may be sent to Mr. A. W. Mayo-Robson, C.V.O., F.R.C.S., Lincoln House, Basil-street, Knightsbridge, S.W.

GRAYLINGWELL MENTAL HOSPITAL, CHICHESTER.—The West Sussex county council's asylum at Chichester, known as the Graylingwell Mental Hospital, is to be taken over by the War Office early in April for a military hospital with accommodation for 1000 wounded. The patients at present in the institution are being distributed as follows: Netherne, 137; Chartham (Kent), 103; Hellingly, 100;

Fareham, 90; Haywards Heath, 80; Barming Heath, 70; Berkshire, 60; Portsmouth (female), 60; Isle of Wight, 50; and Canterbury, 25. Private patients will be removed to Hellingly, Haywards Heath, and Isle of Wight. Dr. H. A. Kidd, the medical superintendent, will be confirmed as chief administrator of the hospital with military rank, and the whole of the existing officers and staff will be retained. There will be a consulting staff of London physicians and surgeons, a visiting staff of surgeons and physicians in the county, in addition to a large resident staff, while the nursing staff will be increased to about 200. The War Office will pay the whole of the expenses connected with the adaptation of the hospital, also the expenses of the removal of the patients.

THE late Mr. Joseph Chamberlain's house, Highbury, at Birmingham, has been placed by Mr. Austen Chamberlain at the disposal of the military authorities for use as a hospital of 125 beds.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates were successful:—

Surgery.—J. R. Crollus (Sections I. and II.), Edinburgh and London Hospital; S. C. Dyke (Sections I. and II.), St. Mary's Hospital; L. A. J. Graham (Sections I. and II.), Cambridge and Guy's Hospital; R. A. Holmes (Sections I. and II.), Guy's Hospital; S. B. King (Sections I. and II.), St. Mary's Hospital; N. W. Rawlings (Section II.), Manchester; H. B. Taylor (Sections I. and II.), St. Mary's Hospital; and A. K. S. Wyborn (Sections I. and II.), Middlesex Hospital.

Medicine.—C. D. Banes (Sections I. and II.), King's College Hospital; A. U. L. Bennett (Sections I. and II.), Royal Free Hospital and Birmingham; S. C. Dyke (Sections I. and II.), St. Mary's Hospital; J. D. Ferguson (Sections I. and II.), Leeds; R. A. Holmes (Sections I. and II.), Guy's Hospital; S. B. King (Sections I. and II.), St. Mary's Hospital; H. B. Padwick (Sections I. and II.), Cambridge and London Hospital; R. Quesada-Jiménez (Sections I. and II.), Guy's Hospital; N. W. Rawlings (Section II.), Manchester; W. H. Rhys-Jones (Sections I. and II.), Charing Cross Hospital; and H. B. Taylor (Sections I. and II.), St. Mary's Hospital.

Forensic Medicine.—B. A. Bull, Oxford and St. Bartholomew's Hospital; J. E. Cheesman and S. C. Dyke, St. Mary's Hospital; J. L. Hamilton, London Hospital; S. B. King, St. Mary's Hospital; H. B. Padwick, Cambridge and London Hospital; R. Quesada-Jiménez, Guy's Hospital; W. H. Rhys-Jones, Charing Cross Hospital; and H. B. Taylor, St. Mary's Hospital.

Midwifery.—B. A. Bull, Oxford and St. Bartholomew's Hospital; and S. C. Dyke and H. B. Taylor, St. Mary's Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—J. R. Crollus, S. C. Dyke, R. A. Holmes, S. B. King, N. W. Rawlings, H. B. Taylor, and A. K. S. Wyborn.

UNIVERSITY OF SHEFFIELD.—The following candidates have passed the Second Examination for the degrees of M.B., Ch.B.:—

Annie Clark, William Collins, Ethel Mary Mathews, and Winifred Hannah Wells (with distinction in Anatomy and Physiology).

UNIVERSITY OF DURHAM (FACULTY OF MEDICINE).—At the second examination for the degree of Bachelor of Medicine the following candidates have passed in Anatomy and Physiology: Ewart Gordon Anderson (second-class honours), James Allan Berry (second-class honours), James Struthers Clark, Leonard Wilfrid Hearn, George Malayramon Kerry, William McDonald Pettigrew, and William Arthur Tweddle.

UNIVERSITY OF BRISTOL.—At the examination for the degree of M.D. Frederick Percival Mackie passed with honours.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on March 11th, Sir Francis H. Champneys being in the chair. A letter was considered from the Clerk of the Council transmitting a copy of a letter from the Midwives Institute embodying a resolution passed by the council of the institute concerning the appointment by local bodies of unqualified and inexperienced women as inspectors of midwives, and inquiring whether the Board has any information justifying the implication conveyed by the resolution. The Board directed that the Clerk of the Council be informed that the Board has no evidence of the appointment on a large scale of improperly qualified women as inspectors

of midwives; one such case has recently come before it. The Board understands from one of its number that the resolution of the Midwives Institute referred to apprehensions in the future rather than to delinquencies in the past. With regard to the future, the Board thinks that it is highly advisable that persons who are appointed to supervise others should have received at least the amount of training possessed by those whom they supervise; otherwise their knowledge is almost sure to be insufficient to command the respect which their orders and advice ought to command. On the other hand, it is impossible to maintain that the mere possession of the Board's certificate guarantees all the qualities desirable in an inspector of midwives. A letter was considered from the medical officer of health of South Shields asking the opinion of the Board upon the position of a midwife who delivers a woman on the instructions and in the absence of a medical practitioner already engaged for the confinement. The Board decided that the reply be that they consider that as regards the relation of the doctor and midwife to the patient no harm is done if the patient clearly understands from the doctor that he will not attend the confinement if normal. If the doctor is engaged to attend the confinement whether normal or abnormal the midwife is acting as a monthly nurse; if she is engaged to attend the case she is acting as a midwife, and is bound by all the rules of the Board. A letter was considered from the county medical officer of health of Lancashire asking the opinion of the Board on his suggestion that it should be obligatory on a candidate for the Board's examination to take a course of three or four months' training in a hospital or in some other approved institution, and that she should not be permitted to receive the whole of her training under the supervision of a midwife who is not necessarily a trained nurse. The Board directed that the medical officer be informed that they have passed a resolution in favour of extending the period of training to six months.

ROYAL SOCIETY OF MEDICINE.—We are asked to state that the meeting of the Section of Pathology announced for March 30th will not be held.

MEETING OF THE BRITISH ASSOCIATION IN SEPTEMBER.—It has been resolved that Manchester will receive the British Association this year, but on account of the war the customary hospitality and entertainments—i.e., the social side—must be curtailed and restricted. The usual sectional meetings for scientific work and the public lectures will be carried through. The meeting will be held in the second week of September. The buildings of the University and those of the Municipal Technical School will be available for the meetings of the sections. The continuity of the meetings of the Association has been unbroken since the Association was founded in 1831.

APOTHECARIES' HALL OF IRELAND.—On St. Patrick's night, March 17th, the Governor, Dr. J. C. McWalter, entertained a large company to dinner in the Gresham Hotel, Dublin, when among the speakers was the new Provost of Trinity College, Dublin, Rev. J. P. Mahaffy, whose great-grandfather, John Pentland, was a member of the original corporation of the Apothecaries' Hall of Ireland.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—At the seventy-fifth annual meeting of subscribers to this hospital held recently, under the presidency of General A. P. Penton, the annual report stated that during 1914 the in-patients numbered 1711, the largest number on record; there were 2163 out-patients. The daily average number of occupied beds was 146. The financial statement showed an income of £8443, and a deficit balance of £2430 remaining against the institution. It was decided to allocate 50 beds for the sick and wounded soldiers, and the committee will accept contributions from the Government and also from the public in aid of this object.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of the above society was held at St. John's Hospital on March 16th, Dr. W. Knowsley Sibley being in the chair. A series of clinical cases were shown by Dr. Morgan Dockrell, Dr. J. L. Bunch, Dr. Knowsley Sibley, and Dr. Simonds Gooding. Mr. A. T. Bremner (Leicester) read a paper entitled "The Importance of Detail in the Treatment of Diseases of the Skin," which resulted in an interesting discussion.

ROSE.—On March 15th, at St. Mary's, Liphook, the wife of Captain A. M. Rose, Royal Army Medical Corps, of a daughter.
SMITH.—On March 16th, at St. Mary's-road, Doncaster, the wife of H. Gordon Smith, M.B., B.S. Lond., D.P.H., of a son.

MARRIAGES.

BOWES—GRAHAM.—On March 5th, at All Souls', Langham-place, W., Richard F. B. Bowes, B.A. Oxon., M.R.C.S., L.R.C.P., to Minnie Johnson Graham, daughter of the late David Graham and Mrs. Graham, of Aspatria, Cumberland.
HOLMES—MASSEY.—On March 22nd, at St. Stephen's, Avenue-road, Regent's Park, London, Thomas Sydney Shaw Holmes, M.B., M.Ch., F.R.C.S. Eng., to Kathleen Louise, youngest daughter of Edmonds Massey, Yew Cottage, Hoddesdon, Herts.

DEATHS.

ALEXANDER.—On March 18th, at Maycroft, Wavertree, Liverpool, David Moore Alexander, M.D., aged 37 years.
DICKINSON.—On March 19th, at Clifton, Wm. G. Dickinson, M.D., late of West Hill, Putney, aged 61 years.
HALL.—On March 14th, at the Military Hospital, Lichfield, Lieutenant H. S. Hall, R.A.M.C., aged 35 years.
HILL.—On March 17th, at Churchfields, Old Basford, Nottingham, William Henry Hill, M.B., C.M. Edin., aged 52 years.
THELWELL.—On March 14th, at Narborough, Leicestershire, Fred. W. W. Thelwell, L.S.A. Lond.
THYNE.—On March 23rd, at 1, Hamilton-mansions, Hove, Thomas Thyne, M.D., F.R.C.S., aged 75 years, late of High Barnet.
WILSON.—On March 24th, at 282, Goldhawk-road, London, Aurora Kate, beloved wife of James Wilson, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

IMPERIAL BUREAU OF ENTOMOLOGY.

THE Earl of Cromer, who was the first chairman of the managing committee of this Bureau, resigned the position recently owing to ill-health, and was succeeded by the Right Hon. Austen Chamberlain, M.P., who has prepared the report for the year 1914, which has just been presented to Parliament. In the course of it Mr. Chamberlain writes:—

"The Bureau has now been established for two years, and I am glad to be able to record the emphatic opinion of the committee that it has more than justified its existence. From many quarters the director (Mr. G. A. K. Marshall) has received appreciation of its work, and there is no reason to doubt that if the necessary funds for its maintenance are obtained it will continue to be of real assistance not only to the Dominion and Colonial Governments, but also to foreign Governments which are closely interested in entomological problems. . . . The publications of the Bureau have been continued. Every month the *Review of Applied Entomology* is published in two parts, one dealing with agricultural entomology, and the other with medical and veterinary entomology. . . . The other regular publication of the Bureau is the *Bulletin of Entomological Research*. This is issued quarterly and contains original illustrated articles. Among the most important published during the year may be mentioned contributions dealing with the bionomics of tsetse-flies by Messrs. R. W. Jack, Ll. Lloyd, R. B. Woosman, and Dr. J. O. Shircove; Dr. R. Roper's paper on the malaria-carrying mosquitoes of British North Borneo; an account of the blood-sucking insects observed by Dr. J. J. Simpson on the Gold Coast; and papers on the agricultural insect pests of Southern Nigeria by Dr. W. A. S. Lamborn and of Nyasaland by Mr. E. Ballard. . . . Two travelling entomologists have been employed in Africa as hitherto, although a period of some six months elapsed between the departure of Mr. S. A. Neave from Nyasaland to take up his duties as assistant director of the Bureau, and the appointment of Dr. W. A. S. Lamborn to succeed him as travelling entomologist in East Africa. Mr. Neave had been stationed at Mlanje for the purpose of studying the life-histories of the blood-sucking flies of the family Tabanidae, many of which undoubtedly play an important rôle in the dissemination of various diseases of domestic animals; and to enable him to carry out his researches a laboratory was built for him by the Government of Nyasaland at his headquarters. He has succeeded in discovering the breeding habits of no less than 20 different species concerning which nothing was known previously. It was at first intended that Dr. Lamborn should proceed to the East Africa and Uganda Protectorates, but on reconsideration the committee felt that his services would be more valuable for the time being in Nyasaland. Accordingly he is now working in that Protectorate, his general objects being to test, by experiment on a fairly large scale, the practicability of eradicating glossina within a given area by direct attacks upon the flies themselves, and concurrently with this experiment to test the actual effects on the fly of clearing undergrowth in order to ascertain whether the clearing really kills the flies or merely drives them elsewhere. It is anticipated that this experiment in destruction of glossina must extend over at least one year if definite information is to be obtained as to the likelihood of catching and trapping operations proving really effective in controlling the numbers of the fly. On the West Coast Dr. J. J. Simpson has been employed on special investigations connected with the glossina problem in the Northern Territories of the Gold Coast. A full account of his previous work in the Gold Coast has appeared in Vol. V. of the *Bulletin of Entomological Research*, and it was hoped that he would have been able to collect some equally useful information in the Northern Territories, but I regret to report that when he had only half completed his tour he was invalided home, and he is now recuperating in this country. Arrangements have also been made for Mr. W. F. Fiske, who had spent a year in Uganda working for the Royal Society, to carry out investigations for the Bureau in that Protectorate. He is at present living on the Sesse Islands in Victoria Nyanza. . . . The importance of the glossina investigations cannot easily be overrated, as, indeed, appears in the Report of the Sleeping Sickness Committee which the Secretary of State for the Colonies appointed to examine the question of the relation between trypanosomiasis and wild animals."

After referring in detail to the operations of the Bureau in other directions, and regretting that comparatively little progress has been made with the stegomyia survey in the

Far East, Mr. Chamberlain states that excellent results have been obtained with the Carnegie studentships, which are generously provided by Mr. Andrew Carnegie for the purpose of enabling young men selected in this country to have an opportunity of studying the American methods of dealing with noxious insects. The conference of the official entomologists of the Empire which it was proposed to hold in July next with the object of discussing various questions which closely concern the interests of the different parts of the Empire, has, owing to the war, been postponed indefinitely, but the committee trust that when circumstances permit the project will be revived.

INVALID CHILDREN'S AID ASSOCIATION.

THE annual meeting of the Invalid Children's Aid Association will be held, by permission of Mr. and Mrs. George Coats, at 11, Hill-street, Berkeley-square, London, W., on Wednesday afternoon, April 28th, at 3 o'clock. Field-Marshal Lord Grenfell will preside, and Bishop Boyd Carpenter, Lady Jellicoe, Countess Ferrers, Dr. A. J. Jex-Blake, and Captain F. Grenfell, V.C., will be among the speakers. Admission will be by ticket only, applications for which may be made to the secretary, 69, Denison House, 296, Vauxhall Bridge-road, Westminster, S.W.

CENTIGRADE AND FAHRENHEIT.

To the Editor of THE LANCET.

SIR,—An equally simple method of conversion and applicable both ways is the following:—

$$C = \frac{(F - 32) \times 5}{9} \quad F = \frac{C \times 9}{5} + 32.$$

I am, Sir, yours faithfully,
March 17th, 1915. PENROSE WILLIAMS.

THE MEDICAL PICKWICK.

THE first two numbers have appeared of an American monthly medical journal which has little to do with the serious side of medicine, but is concerned rather with the lighter aspect of the work of the doctor, the humour of the profession, its anecdotes, and its biography. We may mention a few of the articles which the numbers we have received contain. There is a study of "Moncrief's Receipts," which was published nearly 200 years ago; there is an appreciation of the veteran Dr. Abraham Jacobi; a chapter on a collection of anecdotes of Dr. John Radcliffe; and a report of "The Pickwick Medical Society," a very fair cut at only too many medical meetings; and mingled with these are many medical jokes and anecdotes, some new and sparkling, and some of a hoary antiquity that makes the reader almost regret that they have been disturbed from their well-earned rest, though of course there are always younger members of the profession to whom they may be new. We would like to mention specially an article by Dr. Frank Place on the inaccuracy of medical bibliographical references; all who have had to look up references given in papers or books will know the difficulties encountered, and this article recounts the immense trouble met with in endeavouring to find the original papers in which certain statements were made; the article is entitled "Bibliographical Bones"; etymologists may be interested to learn that in this connexion a "bone" means a mistake.

Many authors have "dropped into poetry." It may be asked, "Why Pickwick?" It is true that the word Pickwick occurs here and there, and the well-known phrase "In a Pickwickian sense" is to be found several times; but there is no attempt to bring out any of the medical aspects of Mr. Pickwick's remarkable memoirs. So far as our memory serves us, Mr. Pickwick himself nowhere expresses any opinion on a medical subject, and his stormy interview with Dr. Payne and Dr. Slammer at the Bull at Rochester and his adventures with Bob Sawyer and Benjamin Allen are his closest relations with our profession that have been recorded. But the title is quite sound if the contributors in future issues live up to it, for the sidelights on early Victorian medicine shed by Dickens in his first great book are illuminating.

MAP OF OPERATIONS IN THE NEAR EAST.

Stanford's atlas maps of the Dardanelles and the Troad and of the Bosphorus and Constantinople are of interest at the present juncture and render intelligible the Admiralty reports of operations. The two maps are on one sheet, 30 in. x 22 in., the former on the scale of 3 miles (1 : 190,080), the latter 1½ miles (1 : 95,040), to an inch. The hill features are clearly delineated, the heights being given in feet; the roads are shown, as well as the principal ruins, fountains and wells, lighthouses, lightships, anchorages, rocks, fathom lines, and direction of currents,

and the forts are marked in red with the reference letters used in the British Admiralty's reports. The maps, price, coloured sheet, 3s. (post free 3s. 5d.), or mounted to fold in case 5s. (post free 5s. 3d.), may be had from Edward Stanford, Limited, Long Acre, London, W.C.

A REMARKABLE BIRTHDAY COINCIDENCE.

To the Editor of THE LANCET.

SIR,—I think it must be an extremely rare event for three members of one family to be born on the same day of the year. On St. Patrick's Day, 1909, I delivered Mrs. B. of a son; on the same day, 1913, I again delivered her of a son; and on Wednesday last I was once more in attendance upon her, when "Patrick the third" began his earthly pilgrimage. I think this triple coincidence in one family is worth recording.

I am, Sir, yours faithfully,
WM. BOURNE HALLOWES, L.R.C.P. & S. Irel.
Newark, Notts, March 20th, 1915.

THE TECHNIQUE OF EFFECTIVE BROMIDE THERAPY IN EPILEPSY.

WE have received from the Hoffmann-La Roche Chemical Works, Limited, of Idol-lane, London, E.C., a reprint of a paper under the above heading which was read by Dr. A. Ulrich before the Medical Society of the Canton of Zürich. He institutes a salt-poor diet and exhibits "sedobrol" in epilepsy. As was pointed out in our analytical columns of July 4th, 1914, sedobrol is a combination of sodium bromide with an appetising bouillon basis. Bromide is thus given in the form of a dietetic, the patient being unaware of the presence of the drug. A free dilution of the bromide is ensured, and the physician is able to give bromide while gradually withdrawing the daily intake of sodium chloride, which can be done without rendering the diet vapid. Sodium bromide possesses a salinity similar to that of common salt.

THE MEDICAL ENTERPRISE SOCIETY, LIMITED.

WE are desired to request any members of the Medical Defence Union who are shareholders or have placed accounts for collection in the hands of "The Medical Enterprise Society, Limited," of 25, Palace Chambers, 9, Bridge-street, Westminster, S.W., to communicate with Messrs. Hempson, of 33, Henrietta-street, Strand, W.C., the solicitors to the Union.

WOMEN POLICE FOR BRIGHTON.

BETWEEN 40 and 50 enthusiastic members of the Brighton and Hove branch of the National Union of Women Workers have formed a corps of women police at Brighton and have been officially recognised. They have commenced active work, and it is considered, with so many soldiers always billeted in the town, and the number of girls ready and willing to talk to strange soldiers, sometimes regardless of consequences, that the women patrols will find many opportunities of doing useful work.

ELECTRO-MEDICAL APPARATUS.

WE have received from the General Electric Company, Limited, of Queen Victoria-street, London, E.C., a copy of their latest list of electro-medical appliances. These include apparatus for electrolysis, epilation, &c., cautery apparatus, medical and dental lamps (laryngeal, ophthalmic), massage outfits, and so forth. A good deal of care appears to have been taken to make these useful appliances convenient, suitable, and economical for the various purposes indicated.

A HOME OF REST AT NOMINAL COST.

"R. F. P." 41, Hallam-street, London, W., writes to ask if any reader knows of a home of rest for a lady, the daughter of a deceased medical man; she is incapacitated from work, having undergone an operation for radical cure of hernia, phlebitis developing, leaving a chronic swelling of the legs which will for a very long time, if not permanently, incapacitate her from earning her living.

INSTITUTION WANTED FOR A CRIPPLED GIRL.

"W. W. L." (Swansea) writes that he is interested in a little girl, 10 years of age, who from birth has been a cripple. She cannot use or control her legs, but is normal in every other way. He asks for the address of some institution where she would be both educated and medically treated, stating that the girl's parents do not know how to deal with her, while they are anxious to do the best for her future. The child's maternal uncle is prepared to meet the expense.

ANTISEPTIC PREMIER PASTE.

THIS adhesive paste has been given a considerable trial in our offices, and we can speak favourably of it. It forms a very useful medium for photographic mounts and for all departments of labelling. It is clean, soft, and sticky, and goes further than many similar pastes owing to its uniformity of composition, for there are no lumps, the starch being thoroughly gelatinised. The whole is kept sweet and free from moulds by the addition of an antiseptic essential oil. It is supplied by the British Manufacturing Company, of Beechcroft-road, Leytonstone, London, N.E.

Mr. Robert J. Hillier, M.R.C.S. (Sheffield), asks whether there is any home for feeble-minded children where a girl of a little over 2 years can be received. She has some paralysis and also occasional epileptiform attacks. She has been under observation for a week in the Children's Hospital, Sheffield, but it is not considered possible to operate. The parents cannot afford to pay.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

SECTION OF PATHOLOGY.—The meeting of this Section announced for March 30th will not be held.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Discussion on the Value of Tuberculin Treatment (opened by Dr. R. M. Leslie (Medical) and Mr. E. Gillespie (Surgical)).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY AND WEDNESDAY.—5 P.M., Arris and Gale Lectures:—Dr. D. Waterston: Further Recent Investigations in the Development of the Human Body.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 3 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 3 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases. THURSDAY.—5.15 P.M., Clinical Lecture.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill-street.—4.30 P.M., Medical and Surgical Cases.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.
TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 1 0	One Year	...	£1 5 0
Six Months	...	0 12 6	Six Months	...	0 14 0
Three Months	...	0 6 6	Three Months	...	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

been remarkable."—BRITISH MEDICAL JOURNAL.

Baillière, Tindall & Cox, 8, Henrietta-street, Covent Garden, London.

MANY VALUABLE LIVES MAY BE LOST UPON THE FIELD OF BATTLE

through slight wounds becoming septic, if efficient First-aid is not forthcoming.

These wounds should be at once washed with a **real germicidal Soap**.

No First-aid outfit is complete without **"ASEP SO"** (Regd.) (COOK'S Antiseptic Soap). It consists of ACTIVE Biniodide of Mercury incorporated with pure Soap. It is sold at 6d. per tablet.

Another Medicated Soap at a lower price (3d. per tablet in Metal box) is **"SCOUT."** This Soap is made from the fruits of the Palm and Pine Trees, and its germicidal value is equal to that of a Soap containing 20% Carbolic Acid.

Special terms to all First-aid, Nursing and Ambulance Societies.

EDWARD COOK & CO., LTD., The Soapery, **BOW, LONDON, E.**

Valentine's Meat-Juice

For **Quieting** the Irritable Stomach, for **Aiding** the Digestion and for **Sustaining** and **Strengthening**, Valentine's Meat-Juice is **Extensively Employed** in the treatment of

Phthisis.

Dr. Gouel, Physician in Chief of the Villepinte Hospital for Consumption, Paris, France: "VALENTINE'S MEAT-JUICE succeeds well in cases of Anæmia and in the treatment of Tuberculosis in an advanced stage when the stomach is intolerant."

Dr. Pietro Borromeo, Physician and Surgeon of the Hospital of Rome, Italy: "I have tried VALENTINE'S MEAT-JUICE in the Tuberculosis Division of the Hospital of the Holy Spirit, and have proved the great advantages that it renders for the nutrition of the consumptive. Pleasant to the taste of the most fastidious of the sick, it does not irritate the stomach; but stimulates the peptogastric functions so as to improve notably the appetite, even in cases of continuous and high fever and of extreme loss of strength."

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY.

RICHMOND, VIRGINIA, U. S. A.

Baillière, Tindall & Cox

CASTELLANI & CHALMERS' Tropical Medicine

“This book has no rival—it is certainly one of the most important contributions that has been made to tropical medicine in recent years.”—JOURNAL OF TROPICAL MEDICINE.

SECOND EDITION. Pp. xxxii. + 1748. With 15 Coloured Plates and 630 Illustrations.

PRICE 21/- NET

STEWART'S Manual of Physiology

“This work maintains its high scientific character, and will be read with advantage by all candidates preparing for their examination in physiology and desiring to obtain a broad grasp of physiological problems.”—LANCET.

SEVENTH EDITION. Pp. xxiv. + 1150. With Coloured Plate and 467 Illustrations.

PRICE 18/- NET

ADAMS & CASSIDY'S Acute Abdominal Diseases

This book, written by a surgeon and a physician in collaboration, deals not only with acute abdominal emergencies of a surgical nature, but also with acute phases of abdominal diseases whether surgical or medical.

Pp. x. + 572. With 28 Illustrations.

PRICE 12/6 NET

McCAW'S Diseases of Children

“We have read this book with some care, and have come to the conclusion that it contains all the information practitioners usually require.”—LANCET.

Pp. xii. + 524. With 14 Plates and Illustrations.

PRICE 10/6 NET

TREDGOLD'S Mental Deficiency

“Indispensable as a trustworthy guide to the most recent scientific and sociological findings in this department of humane activity.”—JOURNAL OF MENTAL SCIENCE.

SECOND EDITION. Pp. xx. + 492. With 67 Original Illustrations.

PRICE 12/6 NET

MAY & WORTH'S Diseases of the Eye

“As a work for the student and general practitioner this is hard to beat.”—EDINBURGH MEDICAL JOURNAL.

It has been translated into French, German, Italian, Dutch, Spanish, and Japanese.

FOURTH EDITION. Pp. viii. + 500. With 336 Illustrations, including 22 Coloured Plates.

PRICE 10/6 NET

FITZWILLIAMS' Operative Surgery, including Surgical Anatomy and Surface Markings.

“We have not seen any work which is better suited for the student or the young practitioner than this.”—LANCET.

Pp. viii. + 450. With 284 Illustrations.

PRICE 10/6 NET

McKISACK'S Medical Diagnosis

A Treatise in Dictionary form on the Signs and Symptoms observed in Diseased Conditions.

“The practitioner will be able to consult it with advantage.”—LANCET.

SECOND EDITION. Pp. xii. + 590. With 76 Illustrations.

PRICE 10/6 NET

LAMB'S Throat, Nose & Ear: a Practical Guide to their Diseases

“A really helpful ‘guide’ in diseases of the throat, nose, and ear. No other work covers exactly the same ground.”—LANCET.

THIRD EDITION. Pp. xvi. + 352. With 2 Plates and 57 Illustrations.

PRICE 7/6 NET

MORISON'S Disorders of the Heart (Motor and Sensory)

“The book merits careful perusal and consideration, as it contains many striking criticisms of current theories and a new marshalling of ascertained facts.”—BRITISH MEDICAL JOURNAL.

Pp. viii. + 262. With 51 Illustrations.

PRICE 7/6 NET

The NATURAL SPANISH APERIENT WATER

RUBINAT-LLOORACH

[FROM THE LERIDA SPRING, SPAIN—LEASED BY A FRENCH COMPANY.]
(Hydragogue, Purgative, and Cholagogue.)

The BRITISH MEDICAL JOURNAL says:—

"Examination showed it to contain no less than 10.3 parts of anhydrous salts in 100 parts by measure, the principal constituent being sodium sulphate; magnesium sulphate, sodium chloride, and calcium sulphate were present in much smaller quantity. The analysis represents the dissolved salts as follows (grams per litre being here converted into grains per fluid ounce):

Sodium sulphate	42.16 grains.	Calcium sulphate	0.85 grains.
Potassium sulphate... ..	0.10 "	Sodium chloride	0.90 "
Magnesium sulphate	1.43 "	Silica, alumina, iron, &c..	0.02 "

In one fluid ounce.

(42.16 grains of anhydrous sodium sulphate represents 95.7 grains of the usual crystallised salt, or 'Glauber's salt'.)

In view of the large amount of purgative salts present, a comparatively small dose suffices, a wineglassful" (fasting).

The Certainty of quiet at all hours of the Day.

A GAS FIRE puts a stop to much noise in the sick-room : the tramping and door opening and shutting that are inevitable when heavy coal-scuttles are brought into the room is no longer necessary : the Gas Fire never has to be poked or made up : there are no cinders to fall, no grate cleaning, no crackling of freshly lighted wood, no smoky chimneys.

A Gas Fire is the only fire that makes it possible to keep the sick-room at an absolutely even temperature : its use should certainly be recommended in all cases of protracted illness.

Full particulars from The British Commercial Gas Association, 47, Victoria Street, Westminster, S.W.

INGRAM & ROYLE, Ltd., 45, Belvedere Rd., London, S.E.

Prescribed by the Medical Profession or 35 years.

The MEDICAL PRESS & CIRCULAR (London, Eng.) says:

"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in his treatment of the sick."

"AN OUTSTANDING FOOD."

Everywhere Benger's is the Food relied upon by the British medical profession, in the prostration of illness, after severe operations, and in cases of difficult feeding.

Benger's is the One Food which contains the active enzymes of natural digestion (the amylolytic and tryptic ferments), and because of these, *it is the One Food* which is self-digestive to any extent the physician may prescribe.

It is a safe food to give in sickness and in severe digestive derangement, and is usually retained when all other foods are rejected.

BENGER'S FOOD (which is to be prepared with fresh new milk) is enjoyed by invalids who are unable to assimilate milk alone or milk and water.

for INFANTS, INVALIDS, AND THE AGED,
is sold throughout the World by Chemists, &c., in sealed tins.

A physician's sample, with full particulars, will be sent post free on application to any member of the medical profession.

depôts throughout Canada.

N.B.—BENGER'S FOOD is the direct outcome of the pioneer work on digestive ferments, by the late Sir William Roberts, M.D., F.R.S., and the late Mr. F. Baden Benger F.L.C. F.C.S. in 1880, since when it has been the premier dietetic preparation of its kind in the British Empire.

Antimeningitis Serum Mulford

FOR THE

Treatment of Cerebrospinal Meningitis

The use of Antimeningitis Serum has been placed on a secure basis by the scientific work of Flexner and others at the Rockefeller Institute, and confirmed by extensive clinical observations. The mortality of the disease is reduced from the usual rate, between 70 and 90 per cent., to about 25 per cent. As with other curative serums, it is essential that Antimeningitis Serum be used early and in sufficiently large dosage. The serum must be introduced directly into the spinal canal, as absorption of fluids from the general circulation into the spinal canal is extremely slow, and it is essential that the serum in high concentration be brought in direct contact with the diplococcus if the best results are to be obtained.

Meningo-Bacterin Mulford

(Meningococcus Vaccine)

and

Meningo-Serobacterin Mulford

(Sensitized Meningococcus Vaccine)

FOR

Immunization Against Cerebrospinal Meningitis

In January, 1913, 68 cases of cerebrospinal meningitis with 44 deaths occurred in Dyer County, Tennessee. During the epidemic there was a total of 145 cases with 80 deaths.

Results of Immunization with Meningo-Bacterin.—Over 10,000 persons were immunized with Meningo-Bacterin. No cases of cerebrospinal meningitis were reported among those receiving the full immunizing treatment.

TOXOL

Manufactured by Boots Pure Drug Co., Ltd.

Responding to the desire of the Medical Profession to discard preparations paying tribute to the enemies of this country, the laboratory staff of Boots, the Chemists (consisting of some 30 highly-trained analysts), perfected TOXOL, which is identical in all but name with "Lysol" as formerly imported from Herren Schulke & Mayr of Hamburg—a solution of cresols in a saponaceous medium—and superior in strength of disinfecting power.

TOXOL is pronounced by medical men who are using it to have all the qualities of "Lysol," and is certified on high authority to excel all samples of "Lysol" in disinfecting co-efficient.

*Copy of Report by Dr. SAMUEL RIDEAL, joint-originator of the RIDEAL-WALKER
Co-efficiency Test. November 16, 1914.*

"I have purchased at one of your branches samples of TOXOL, and my results on examination confirm your labelled strength that it is two and a half times as powerful as Phenol, and it is higher than all samples of 'Lysol' I have examined." (Signed) SAMUEL RIDEAL.

The following are extracts from the letters of Medical Men who have already used TOXOL to replace "Lysol":—

"It seems to be in every way quite satisfactory and an excellent substitute for 'Lysol.'"

"Very glad to test and prove that English science is as good as that of the Barbarians. It would be a good thing to circularise the profession with a list of alien enemies' products."

"I tried it on a septic finger and found it all you stated it to be."

"TOXOL is very satisfactory. The medical profession ought to feel grateful to Sir Jesse Boot for replacing a German article in such a prompt and satisfactory manner."

"Am using sample and I am so pleased with it that I shall continue to use TOXOL in future."

"An excellent preparation. I obtained 'Lysol' many times from Hamburg before any English chemist would stock it, so am interested in your venture."

"Dr. — is pleased to see an English manufacturer superseding a German product, and he will give his support to such a company as will do this."

"Many thanks; have used solutions of TOXOL in various strengths for numerous minor surgical cases with most satisfactory results."

"Will give TOXOL a trial. Am much interested in finding that your firm has succeeded in making a preparation in England of a German make like 'Lysol.' It is much more efficient than the German."

"Superior to 'Lysol' as far as I have tried it."

**Samples of TOXOL will be delivered free on application to
Medical Men who have not yet tested it.**

*TOXOL is sold in 6½d., 11d., 1s. 7d., and 2s. 9d. bottles at all branches of
Sent carriage paid to any Medical Man at above prices; address Boots, M.O. Nottingham.*

Special Bulk Terms to Hospitals and Institutions.

Vitafer

A Message to the British Medical Profession.

VITAFER is ALL BRITISH, the Directors and Shareholders are, and always have been, British. The Casein is manufactured at our own specially equipped factory at Solohead, near Tipperary, and the Glycerophosphates at our Laboratories at Saltley, Birmingham.

VERY few (if any) members of the Medical Profession will now care to prescribe preparations originated in Germany.

This is the more unnecessary as they have available in VITAFER a first-class Food of the same character, which is not only equal to the German articles in nitrogenous nutriment, but is superior in that it contains the whole of the Milk Protein (casein and lactalbumen).

Further not only does VITAFER contain the Glycerophosphates of Sodium, but also those of Calcium and Magnesium, the latter of which counteracts the tendency to constipation which generally follows the use of concentrated foods.

VITAFER is not new, but has been growing in favour with the Medical Profession for several years past, and upwards of 100,000 samples have been distributed to the Profession and the Public during that time. It may truly be described as a carefully thought out and well balanced preparation superior to anything on the market.

**VITAFER is sold at prices which bring it within the reach of all classes. In Tins,
2 oz. 1/3 4 oz. 2/- 8 oz. 3/6 16 oz. 6/-**

AN EFFICIENT SEDATIVE

OMNOPON

TRADE 'ROCHE' MARK

'OMNOPON' Roche, which was originated by Professor Sahli of Berne University in the year 1909, has now won an established place in medicine. It represents the total alkaloids of opium minus its objectionable ingredients. 'Omnopon' is an ideal hypnotic, and possesses the following advantages:

POSITIVE.

'Omnopon' is a light brown powder, soluble in water. Is five times the strength of opium—is perfectly standardised. May be administered conveniently and in exact doses, either internally or as a non-irritating hypodermic solution.

FOR SHOCKLESS SURGERY.

'Omnopon' is largely used as an adjuvant to general inhalation anæsthesia. Prevents post-anæsthetic vomiting.

IN PULMONARY TUBERCULOSIS.

"The purposeless, irritating, dry cough rapidly yielded to gr. $\frac{1}{8}$ th every 4 hours."

(Report of the Mill Road Infirmary, Liverpool.)

NEGATIVE.

'Omnopon' does not produce nausea.

Has no depressant action upon the respiratory centre.

Unlike Morphia, does not give rise to the drug habit.

Prescribed in the doses indicated for bronchial symptoms does not constipate.

SQUIRE'S POCKET COMPANION

TO THE BRITISH PHARMACOPŒIA, 1914.

Published by J. & A. CHURCHILL, 7, Great Marlborough St., London, W.

A systematic record of the alterations and additions to the new B.P.

A veritable VADE-MECUM for the PRESCRIBER.

The LANCET says: "*THE POCKET COMPANION* shows evidence of considerable judicious forethought in the selection of data likely to be of service to a wide class of readers."

The BRITISH MEDICAL JOURNAL says: "*Sufficient has been said to show that the contents of this POCKET COMPANION fully justify its name; it can be strongly recommended to practitioners.*"

SQUIRE'S GLYPHOCAL SERIES.

GLYPHOCAL

SQUIRE'S COMPOUND GLYCEROPHOSPHATE SYRUP.

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

The celebrated Compound Syrup of the Glycerophosphates which is now prescribed with such immediate and striking success in NEURASTHENIA and in all nervous affections accompanied by gastric weakness.

GLYPHOCAL WITH STRYCHNINE

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

An invaluable tonic during CONVALESCENCE.

GLYPHOCAL WITH FORMATES

DOSE—One to two fluid drachms = 3·6 to 7·1 c.c.

SQUIRE'S GLYPHOCAL WITH FORMATES introduces a novelty in the shape of a combined nerve and muscle tonic. It supplements the valuable therapeutic properties of the Glycerophosphates with the muscle-tonic virtues of the Formates.

GLYPHOCAL WITH FORMATES AND STRYCHNINE is of special value as a tonic in abdomino-pelvic pain in women.—*Practitioner*.

Illustrated descriptive leaflet of the full series and samples gratis on application.

TWO CASES TREATED WITH PHYLACOGEN.

(Reprinted from GUY'S HOSPITAL GAZETTE, January 30th, 1915.)

"The following notes of two cases I have recently treated with Phylacogen may be of interest:—

CASE 1.—C. S., female, aged 51. Unmarried, tailoress by trade.

For some five or six years has had sharp attacks of pain in various joints—apparently typical 'flitting pains'—but says she has never had rheumatic fever. For twelve months wrists and ankles have been continuously affected—walking and movement of wrists causing pain. Much limitation of movement.

In September, 1914, went to an English spa for a course of treatment. General health improved, but the joint condition worse on her return.

On examination.—December 12th, 1914, both wrists show periarticular swelling; right wrist nearly completely fixed; typical fusiform swelling of fingers and ulnar deviation at both wrists. Complains of pain, especially in right wrist. Ankles painful. The patient walks 'like a cat on hot bricks'—very gingerly. Left ankle has movement very limited, foot flat and apparently forced upwards between the two malleoli. Pain in both feet and ankles on movement. Knees and shoulders creaked slightly, and have been painful, but they are affected much less than ankles and wrists.

On December 14th, 1914—1 c.c. Rheumatism Phylacogen injected subcutaneously, and daily injections were given from this date, increasing by 1 c.c. daily.

On the third day, December 17th, improvement was obvious in wrists, both in diminution of swelling and increase in range of movement. Reactions caused were slight until the fifth day, when there was considerable fever with headache and malaise lasting a few hours.

8th day, December 22nd. Practically no reaction after the dose of 9 c.c.

9th day, December 23rd. 5 c.c. given.

December 24th. Patient was allowed to sit up out of bed, and the next day she went out.

December 28th.—There is less swelling round the wrists—which can both be fully flexed passively though with some pain. The fusiform swelling of the fingers is much less marked. Active and passive movements of ankles nearly normal. Gait still abnormal.

Patient is to do simple exercises, such as rising on the toes, flexing and extending wrists, &c., for twenty minutes night and morning, and her sister also applies a very amateur form of massage for ten minutes a day to ankles and wrists.

January 16th, 1915. Five weeks from commencement of treatment.

Full flexion of wrists passively. Two thirds of full activity. Practically no pain. No fusiform swelling of fingers—ulnar deviation less marked. Some swelling of wrists still visible. Gait improved. Can walk some miles without pain. Occasional aching results if she walks far

but only slight and infrequent. Can sew with ease. General health very greatly improved—says 'life seems quite different,' and is told by her friends she appears ten years younger.

CASE 2.—M. P., male, aged 50, clerk. First seen December 19th, 1914. When he had a large broken carbuncle below the angle of his right scapula. Has had several others before, the last being four months ago. Has had several attacks of gout. Urine shows no sugar. The present carbuncle has much induration around it and is very painful. There is a small infected spot on the right shoulder. General condition fair, but some nausea and malaise. Fomentations applied four hourly.

December 22nd, 1914. 1 c.c. Mixed Infection Phylacogen given subcutaneously.

December 23rd. 2 c.c. M. I. P. given.

December 24th. 3 c.c. M. I. P. given. The ulceration has not progressed and the 'core' is looser and cleaner. General condition improved.

December 26th. 3 c.c. M. I. P. given.

December 28th. 4 c.c. M. I. P. given. Marked reaction followed—vomiting and headache lasting a few hours.

December 29th. 5 c.c. M. I. P. given. Marked improvement. Induration almost nil, good discharge from 'core,' healthy granulations. General condition very much improved.

December 30th. 2 c.c. M. I. P. given. The last injection, no discharge at all—ulcer quite clean.

January 3rd and 6th. Fomentations have been used throughout, ulcer healing rapidly, no pus, no induration.

January 13th, 1915, ulcer completely healed, some blueness of skin around but otherwise a healthy scar.

These two cases show well the use of Phylacogen in what are usually very tiresome cases. Without it the first case—one of rheumatoid arthritis—would in all probability have gone from bad to worse. None of the ordinary treatments had been of any avail.

The second case—that of carbuncle—was saved much discomfort, and was able to resume his business within three weeks; indeed, he might have done so in ten days. His last carbuncle had taken over six weeks to cure, and had caused him a great deal of suffering and left him very 'run down.' Both the patients are now following their usual occupations, and both state that they feel better than they have felt for a long time."

Other reports showing the value of Rheumatism Phylacogen in rheumatic conditions, and of Mixed Infection Phylacogen in skin infections and septic conditions generally will be found in our booklet, "Phylacogen Therapy," a copy of which we shall be glad to send to any medical man on request.

A Powerful Antiseptic, Disinfectant and Deodorant.

Dioxogen
(Trade $H_2 O_2 12v$ Mark)

For use in Medicine, Surgery, Dentistry and Hygiene.

"Dioxogen" is the one reliable Peroxide of Hydrogen. It may be said that "Dioxogen" costs more than ordinary Peroxide (the kind that is sold because it is cheap), and that the substitute is 'just as good.'

Compare ordinary Peroxide with "Dioxogen."

Ordinary cheap Peroxide contains acetanilid to make it keep. Acetanilid is a questionable drug—so questionable that in the United States the government requires that its presence be noted on the label.

"Dioxogen" is PURE peroxide of hydrogen and contains no acetanilid—"Dioxogen" keeps without it. "Dioxogen" is prepared by special and unique machinery; it is the result of many years' manufacturing experience and is unrivalled for purity, uniformity and constancy of composition.

Ordinary Peroxide quickly deteriorates—Acetanilid is added to prevent this *as much as possible*, but it soon turns rank and bitter—easily recognised by taste and smell. Acetanilid may assist poor peroxide to *keep*, but it does not make it good. Without acetanilid ordinary Peroxide will not keep.

"Dioxogen"—the PURE peroxide of hydrogen—needs no acetanilid to preserve it. "Dioxogen" never turns rank nor tastes bitter, no matter how old it is. "Dioxogen" is always the same—uniform in strength and quality.

Sample and descriptive pamphlet sent free on request.

"One of the most popular Tonics of the day."
—B.M.J.

THIS preparation combines the nutritive and digestive principles of the finest malt extract with hypophosphites, a powerful nerve tonic food. It is superior to the official syrup, and in many years' clinical experience has given most gratifying results.

"Byno" Hypophosphites improves the appetite, reinforces the digestion, and provides easily assimilable nutrition for the tissues. It is a valuable food which conserves the vitality of the nervous system.

EXPLANATORY PAMPHLET
—AND SAMPLE—
FREE TO MEDICAL MEN.

Allen & Hanburys Ltd
Lombard Street, London.

Niagara Falls, N.Y. Toronto. Buenos Aires. Durban. Sydney.

Special Advantages

- 1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.
- 2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.
- 3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.
- 4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.
- 5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.
- 6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

Milk Food No. 1
From birth to 3 months.

Milk Food No. 2
From 3 to 6 months.

Malted Food No. 3
From 6 months upwards

The "Allenburys" Rusks (Malted)

A valuable addition to baby's dietary when 10 months old and after.

A descriptive Pamphlet, giving Analyses, etc., and Samples of the Foods will be sent on request.

Bronamalt

An IDEAL TONIC FOOD

A combination of the active principles of VIBRONA with a highly concentrated preparation of Malt in place of wine.

BRONAMALT possesses both Tonic and Nutrient properties, and thus presents obvious advantages over Malt and Cod Liver Oil.

In cases of impaired nutrition, either in children or adults, BRONAMALT is an invaluable adjunct to the daily dietary.

"According to our experiments, the malt extract used is a very active one, since we found that BRONAMALT digests completely in one hour, at blood heat, 15 times its weight of starch." *The Lancet.*

"In tuberculosis and in other cases of malnutrition and debility predisposing thereto, and for delicate children and unstable adolescents, BRONAMALT can be strongly recommended." *The Tuberculosis Year Book, 1913-14.*

TEXTURÆ ANTIQUÆ, 125—ARAB

'TABLOID' BRAND

(Trade Mark)

Aspirin

QUALITY is always Burroughs Wellcome & Co.'s first consideration. The acetylsalicylic acid used in 'TABLOID' Brand ASPIRIN has a melting-point considerably above that required by the B.P., and reaches a much higher standard in freedom from metallic impurities. The word 'TABLOID' safeguards prescriber and patient against inferior Aspirin.

'TABLOID' Brand ASPIRIN, gr. 5 and 0.5 gramme, is supplied to the Medical Profession as follows: gr. 5, bottles of 25, at 1/0 and 100 at 3/0; 0.5 gm., bottles of 25 at 1/4, and 100 at 4/0 per bottle.

'TABLOID' BRAND

(Trade Mark)

Hexamine

HEXAMINE B.P. (Hexamethylenetetramine) is a diuretic, uric acid solvent and genito-urinary antiseptic. Its antiseptic properties also manifest themselves in the saliva, sputum, sweat, blood and cerebro-spinal fluid. The Hexamine used in the 'TABLOID' product is made by Burroughs Wellcome & Co. at Dartford, Kent, and is of 100% purity, whereas the standard of the new B.P. is only 98%.

'TABLOID' Brand HEXAMINE, gr. 3 and gr. 5, is supplied to the Medical Profession as follows: gr. 3, bottles of 25 at 6d., and 100 at 1/6; gr. 5, bottles of 25 at 8d., and 100 at 2/0 per bottle.

TRADE MARK

'TABLOID' BRAND

Thyroid Gland
(STANDARDISED)

CLINICAL experience proves its reliability in replacing the normal thyroid secretion. It represents the complete activity of the healthy gland.

'TABLOID' Brand THYROID GLAND is supplied to the Medical Profession, in bottles of 100 as follows: gr. 1/10, 6d.; gr. 1/4 and gr. 1/2, 1d.; gr. 1 and 0.05 gm., 11d.; gr. 1-1/2 and 0.1 gm., 1/2; gr. 2-1/2, 1/6; gr. 5 and 0.3 gm., 2/0 per bottle.

"MALTINE"

"MALTINE"

with

COD LIVER OIL.

FORMULA:—70 per cent. of "MALTINE" Plain; 30 per cent. of pure Cod Liver Oil.

"Maltine" with Cod Liver Oil is **Diastasic** (one part converts four of starch) as well as a source of Oil. It is Fluid, Non-Separable, Absolutely Palatable, and will be retained and assimilated when all other forms of cod liver oil are rejected.

Patients rapidly put on weight under a course of this standard preparation.

"MALTO-YERBINE."

("MALTINE" combined with the active principle of YERBA A.V.A.)

Each Fluid Ounce contains the active principle of 30 grains Yerba Santa.

DOSE.—From a teaspoonful to a tablespoonful three to six times a day.

A Stimulating and Liquefying Expectorant.

Indicated in Coughs, Colds, Asthma, Bronchitis, and Difficult Expectoration.

Specially useful in Post-Catarrhal and Influenzal Coughs.

"MALTINE"

with

CREOSOTE.

Each Fluid Ounce contains Pure Beechwood Creosote, 4 minims.

DOSE.—Adults: From a teaspoonful, gradually increasing up to a tablespoonful, after meals. Children in proportion.

This product is free from the two great drawbacks that usually attend the administration of Creosote. It masks the unpleasant acrid taste of the drug, and its ingestion is followed by no disturbance of digestion.

"MALTINE" WITH CREOSOTE is a bland and soothing preparation, and the Creosote, being uniformly distributed through the menstruum, is presented evenly to the absorbing surface, and is free from irritating effect.

List of "Maltine" Products.

- "MALTINE" Plain.
- "MALTINE" with COD LIVER OIL.
- "MALTINE" with PEPSIN and PANCREATIN.
- "MALTINE" with CREOSOTE.
- "MALTINE" with PHOSPHATES.
- "MALTINE" with CASCARA SAGRADA.
- "MALTINE" with IRON.
- "MALTINE" with HYPOPHOSPHITES.
- "MALTINE" with EASTON'S SYRUP.
- "MALTO-YERBINE."

In ordering, kindly specify in writing, "MALTINE COMPANY."

Will be pleased to send Samples Free of Charge to Medical Men.

MADE IN AUSTRALIA

"EUMENTHOL" TOOTH POWDER (HUDSON)

A fragrant, palatable, non-toxic, non-irritant germicidal powder, being a combination of Formalin, Menthol, &c., with a diatomaceous earth in conjunction with a pure high-grade peroxide (MgO_2). The Menthol is in chemical combination with Formalin to form the new antiseptic compound, Dimethol-Formal, $CH_2 (C_{10}H_{19}O_2)$ M.P. 56, 5°C. (Brochet), and unites an antiseptic action twice more powerful than Sublimate, with a very decided effect in hardening the Gums. A strength of 1 in 1000 kills all the salivary bacilli in less than two hours. Dessirier recommends Dimethol-Formal for the treatment of aphthæ.

"Eumenthol" Tooth Powder on dissociation (in contact with water or the Oral Fluids) liberates free active Oxygen, and Hydroxide of Magnesia (Milk of Magnesia) in a minutely divided state is produced.

THE LANCET states: "This Tooth Powder is designed on sound principles and is very agreeable to use. The distinctive feature about it is that, in addition to some approved germicides, it contains MgO_2 , which readily parts with free oxygen, as our experiments have shown."

CONDY'S FLUID

The Pioneer Oxidant,

"AT THE FRONT"

CONDY'S FLUID disinfects and cleanses Wounds, Sloughing Wounds, Burns, Ulcers, Gangrene, Bedsores, &c.; prevents Tetanus and Wound Infections. It establishes and maintains odourless aseptic conditions without causing irritation, all its effects being benign, soothing, and wholesome.

Hydrogen Peroxide, the other available oxidant, is very painful as a dressing owing to the acid added to it as a preservative.

CONDY'S FLUID is free from potassic permanganate, the incautious use of which has caused deaths (16 Coroner's Inquests) and many minor injuries.

*Proper directions for 150 uses
with every bottle.*

CONDY'S FLUID WORKS,

65, GOSWELL ROAD, LONDON.

Consisting of nearly pure PEPTONE and EXTRACTIVES from the ARTIFICIAL DIGESTION of MEAT.

Five Suppositories contain the Extractive of 20 ounces of Meat in addition to the Peptone.

R. H. BOUCHIER NICHOLSON, Esq., Hull Infirmary, in a case of Gastrostomy, says:—"The Beef Suppositories made by SLINGER & Son, York) were of much benefit, the man saying he felt great comfort from their use. The man was saved the pangs of starvation from which he was fast sinking when I first saw him."

Manufactured only by RAIMES & CO. (Successors to SLINGER & SON), Wholesale Druggists, York. Wholesale Agents: Messrs. NEWBERRY & SON, 27 & 28, Charterhouse-square, London, E.C. May also be had of all Wholesale Druggists and Chemists/Sundrymen.

Huxley's Syrup

Formates with Glycerio-Phosphates

A bright cherry-coloured syrup, flavoured with Seville orange peel.

Contains:—*Acid Glycerio-phosphates and Formates of Lime, Soda, Potash, Iron, and Manganese (5 grains in 1 drachm) with or without Strychnine Glycerio-Phosph. $\frac{1}{10}$ gr.*

The Formates have general tonic and stimulant effects, especially noticeable when used in conjunction with the glycerio-phosphates in

NEURASTHENOID or NEURASTHENIC STATES

or in abnormal fatigue from over-exertion, mental or physical.

Original bottles, $\frac{1}{2}$ -lb. or 1-lb. Free sample to Profession.

ANGLO-AMERICAN PHARMACEUTICAL COMPANY, Ltd., Croydon.

Nourry's Wine
(Iodinated.)
0.37 gr. of Iodine and 1.54 gr. of Tannin per tablespoonful.

THIS THOROUGHLY RELIABLE and uniform preparation is prescribed by the most eminent British and Continental Physicians in cases of

**LYMPHÆMIA. ANÆMIA.
DYSMENORRŒA.
PULMONARY AFFECTIONS:**

Children—One to two teaspoonfuls. Adults—One tablespoonful. To be taken at meals twice a day.
Free from Alkaline Iodides. Palatable. Easily assimilated.
A perfect substitute for Cod Liver Oil and Iodides.

For Reports see "BRITISH MEDICAL JOURNAL," January 12th, 1895; August 29th, 1896;
"LANCET," January 6th, 1894; March 30th, 1901, and various other medical publications.

NOURRY'S WINE is NOT advertised to the public.

Sample and literature sent free to Medical Men on application.

CACODYLATE OF SODIUM (CLIN) (Organic Arsenic).

Emphatically recommended by Professors GAUTIER, RENAULT, LETULLE, &c., in the treatment of

**TUBERCULOSIS (either incipient or declared),
IMPALUDISM, DIABETES,
DERMATOSES and CANCER.**

DROPS.—5 drops contain $\frac{1}{4}$ grain of Pure Cacodylate of Sodium.

GLOBULES.—This special form consists of little Globules, easy to swallow, with a shell of gluten. Each Globule contains $\frac{1}{4}$ grain of Pure Cacodylate of Sodium.

TUBES (Sterilised for Hypodermic Injection).—Each Tube contains a sterilised solution dosed at $\frac{1}{2}$ grain of Pure Cacodylate of Sodium per injection of 16 minims.

F. H. MERTENS, 64, Holborn Viaduct, London, E.C.

ENÉSOL

(Salicylarsinate of Mercury).

AN IDEAL COMPOUND for Combined ARSENO-MERCURIAL TREATMENT.
Superior to all others on account of:

1. Its slight Toxicity, rendering possible the administration of comparatively large doses of mercury and arsenic without setting up intolerance.
2. Injections Painless even in full doses. Never causes induration.
3. Double specific action (mercurial and arsenical).
4. Is presented in the form of a 3 per cent. sterilised solution put up in 3 c.c. tubes for hypodermic injection. Each 2 c.c. tube corresponds to about one grain of the anhydrous salt. Sold only in Boxes of 10 tubes.

M. I. 96.

INFLUENZA

BRONCHITIS COLDS FEVERS

BISHOP'S HYDROPYRIN

SOLUBLE LITHIUM ACETYL-SALICYLATE

Is PROMPT and DEFINITE in action.

Antipyretic.—HYDROPYRIN effects most rapid temperature reduction. The fall begins about 15 minutes after administration, reaches the minimum within the first hour, and lasts for three to four hours, at expiration of which period the dose should be repeated.

No Harmful By-effects.—HYDROPYRIN, being freely soluble, passes at once through the stomach unchanged, and therefore, unlike the insoluble acetyl-salicylic acid, which splits off its salicylic acid in the stomach, HYDROPYRIN never causes gastric irritation, nausea, or loss of appetite. HYDROPYRIN has no harmful effect on the heart or kidneys, and does not cause ringing in the ears.

Analgesic.—HYDROPYRIN speedily allays the muscular and joint pains of Influenza, as well as of Rheumatic and Gouty Disorders, and promptly relieves Headaches.

Diaphoretic.—HYDROPYRIN causes gentle, but not profuse, perspiration.

The Complete Solubility of HYDROPYRIN in water and alcohol permits of its administration in syrups, infusions, tinctures, and all other alcoholic or aqueous solutions, wherein HYDROPYRIN is exhibited in a form to ensure its immediate absorption and full activity.

Kalmopyrin, the corresponding Calcium Acetyl-salicylate, possesses the same therapeutic properties as HYDROPYRIN, and is also freely soluble.

BISHOP'S HYDROPYRIN and KALMOPYRIN are free from all the faults and defects of acetyl-salicylic acid, and are much more efficient, reliable, and successful antipyretics, analgesics, and anti-rheumatics. Their introduction has overcome the last obstacles to the satisfactory administration of the salicylates, and both salts are now widely prescribed for Muscular and Articular Rheumatism, Polyarthrititis, Neuritis, Sciatica, Gout, Lumbago, Influenza, and all Feverish Conditions, Colds, Catarrhs, Bronchitis, Headaches, and Neuralgia.

THE LANCET says:—"The preparations seem well adapted for the administration of salicylic acid. The absorption of salicylic acid begins in the alkaline intestinal fluid, and there is, therefore, no irritation in the stomach."

Samples and Descriptive Literature sent Post Free to Medical Men by the Patentees and Sole Manufacturers of—

GOLD MEDAL, INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913. MIST. HEPATICA CONC. (HEWLETT'S)

COMPOSITION.—Ext. Cascarae, Ext. Rhel, Jalapin, Podophyllin, Cocalnae Hydrochlor., 1-12th gr. in each fluid drachm.

THIS excellent compound, first introduced as a general aperient and cholagogue, has now become a popular remedy, and attention has very recently been called to the value of the mixture, by various authorities, in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. The remedial value of the compound depends chiefly upon the power which it possesses in influencing the action of the liver and other glandular organs of the alimentary canal. The remedy would not seem to be indicated in Hepatitis with high fever, so much as in the more chronic form of the affection which ends in enlargement and induration of the organ. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit. Even in the early stages of cirrhosis, whilst the liver is still enlarged, the compound should be regularly given, as great benefit has been derived from its use.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease, and in pregnancy, or in the constipation due to sedentary habits, to habitual overwork (especially of the nervous system), to a deficiency of intestinal secretion, and of peristalsis, and a paralytic state of the intestinal muscular fibres, the mixture can be prescribed with wonderful effect, positively curing cases that have resisted other remedies.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient, and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

Please write: "Mist. Hepatica Conc. (HEWLETT'S)" to ensure obtaining this Preparation.

Obtainable from all Wholesale Druggists and the leading Dispensing Chemists throughout the United Kingdom, India and the Colonies.

THE DIETETIC VALUE OF COCOA

Of the beverages in common use (Tea, Coffee and Cocoa), Cocoa is the best, because—

1. It is not a mere stimulant: it is also a true food.
2. Its stimulant value is similar to that of Beef Tea, and its nutritive value bears comparison with that of milk.

It is quickly absorbed in the stomach, leaving no undigested irritant residue, and is therefore pre-eminently suitable for invalids—

—Van Houten's Cocoa.—

DUNVILLE'S

V R

The Whisky of Uniform Quality

WHISKIES that are so uniform in quality as DUNVILLE'S are rarely found. On February 8th, 1908, "THE LANCET" published a particularly complete Analysis of these Whiskies. On the 14th of March, 1914, 6 years later, the same journal remarks (in connexion with the fresh Analysis): "Both specimens evidenced maturity and possess that peculiar flavour characteristic of genuine Irish Whisky. The Standard quality of these whiskies is evidently maintained."

It is the constancy of quality and superiority that has made Dunville's the most popular of Irish Whiskies.

DUNVILLE'S WHISKIES have been examined and passed, and are exhibited by the INSTITUTE OF HYGIENE at 34, Devonshire-street, Harley-street, London, W., where they may be examined and their merits explained.

BULLOCK'S PEPSINA PORCI.

DOSE—2 to 4 GRAINS.

ACID GLYCERINE OF PEPSINE

DOSE 1 to 2 DRMS.

(BULLOCK).

In this preparation advantage has been taken of the solubility of Pepsine in Glycerine to produce a convenient and desirable liquid form of this valuable medicine; whilst the preservative qualities of the menstruum confer upon the Acid Glycerine of Pepsin the property of keeping for any length of time.

May be prescribed with most substances compatible with Acids.

In 4-oz., 8-oz., and 16-oz. Bottles, and in Bulk.

The published experiments of G. F. DOWDESWELL, Esq., M.A. Cantab., F.C.S., F.L.S., &c., Dr. PAVY, Professor TUSON, the late Professor GARROD, Dr. ARNOLD LEES, and others, conclusively demonstrate the excellence, high digestive power, and medicinal value of the above preparations.

J. L. BULLOCK & CO., 3, Hanover St., Hanover Sq., London, W.

Glycolactophos

This preparation being British, inability to obtain supplies need not be anticipated.
FORMULA.—Casein 95%, Glycerophosphate of Sodium 2½%, Glycerophosphate of Calcium 2½%.

Its use is indicated in the treatment of Neurasthenia, Tabes Dorsalis, Neuralgia, Nervous conditions in which an excess of phosphates are excreted in the urine, Phthisis, Chronic Dyspepsia, Anæmia, Insomnia, and wasting diseases generally. The presence of the Calcium salt gives it a high therapeutic value in the treatment of Rickets.

A NATURAL Health Food, Highly Nutritive, Easily Digested

There can be no doubt of the nutritious character of Banana Flour. The starch in it is peculiarly easy of solution and digestion in the alkaline digestive juices of the body. Banana Flour is readily dissolved, for example, by saliva. It is eminently the food for those of weak or impaired digestion.

"BANANINA" possesses all the properties of Perfect Food combined with pleasant appearance and flavour when made up as directed. It contains the requisite amount of Nitrogen Carbon Fats and Mineral Salts in a form easy of digestion and assimilation.

"BANANINA" is richer in proteid than Foods with Wheat Flour as a basis, and it also contains more fatty matter, consequently its nutritive value is decidedly higher than that of Wheaten Flour.

As a source of energy and material for tissue repair, "BANANINA" stands above all other foods. By reason of its fruity nature it is anti-scorbutic. When prepared as per directions it is a **pre-digested** food for infants.

"BANANINA" has already received the endorsement of the Medical Faculty and Professional journals.

APPLEBY'S "PURE" BARLEY FLOUR.

Unexcelled in purity and quality. Specially treated so that it is perfectly soluble, a particularly important point. Makes a highly nutritious food or refreshing and cooling beverage.

A point of importance is that "BANANINA" and APPLEBY'S "PURE" BARLEY FLOUR have not been chemically treated—thus all the natural food properties are retained. Equally valuable in Nursery, Sickroom, and Kitchen.

We will gladly send any Doctor a testing sample so that he can form his own judgment.

BANANA BREAD FLOUR FOOD LIMITED, Cereal Court, 16, Brunswick Street, LIVERPOOL.

PROTEIN NERVE FOOD

A PURE CASEIN FOOD containing 84% Proteid with Organic Phosphates.

Useful in NEURASTHENIA, NEURITIS, and all cases of IMPAIRED NERVE ACTIVITY.

In Boxes, 1/6, 2/6, and 4/6
Vide 'Lancet,' March 9th, 1912, page 658.

Prepared by R. HOGG & SON,
1, Southwick St., and 40, Connaught St., Hyde Park.

[Registered Trade Mark]

Composition of SECWA.

Moisture	...	...	...	1.20
Fat	...	...	...	.27
Soluble Lact-Albumen	...	...	...	14.25
Mineral Matter	...	...	...	9.80
Milk Sugar	...	...	...	74.45

A LIVING FOOD which contains all the original enzymes in an unaltered condition, and consequently can be employed as an exclusive food for infants without fear of inducing scurvy or other disturbances of nutrition due to the absence of Vitamines in their vitalised elements.

From "THE LANCET," 9th May, 1914—

"We find that SECWA is correctly described. SECWA is a sound preparation on scientific lines and should have obvious uses in special dietetics."

BATTERSEA, LONDON, S.W.

FOR NURSING MOTHERS

YOUNG CHILDREN (over six months old), and ALL PERSONS of WEAK DIGESTION.

GRANSALO

is an invaluable food, highly nutritious, appetising, and exceedingly easy of digestion.

GRANSALO

contains all the essential ingredients of a wholesome dietary, scientifically proportioned, to make it a PERFECT FOOD.

GRANSALO

is already cooked by a process which effectually ruptures the starch granules and renders the food exceedingly easy of digestion.

Analysis and Report by Dr. T. W. DRINKWATER, Edinburgh.

Per cent.	Per cent.	Per cent.
Moisture 8.02	Albumenoids 15.75	(Nitrogen 2.52)
Fat 10.80	Carbohydrates 64.64	(Soluble 18.65)
Fibre 0.08	Ash 0.81	((P ₂ O ₅) 0.883)

This food would be suitable for any Infant over six months old. It is rich in nitrogenous material, and some of this is soluble. The phosphorus is present partly in the form of lecithin, and is a valuable food constituent. It is very miscible in water.
(Signed) THOS. W. DRINKWATER.

A REAL SEA BATH IN
YOUR OWN ROOM.

TIDMAN'S SEA SALT.

[PATRONISED BY THE
ROYAL FAMILY.]

TIDMAN'S SEA SALT is shown by observations made by the authorities at the Natural History Department of the British Museum and at the Zoological Gardens, Regent's Park, to produce REAL SEA WATER. Sea Water is now known to be distinctly RADIO-ACTIVE, containing a definite quantity of RADIUM, with all its marvellous potentialities in the preservation and recovery of good health.

Baths of this celebrated remedy can be used at any convenient temperature and are remarkably effective in all cases where Sea Bathing is desirable—viz., for every form of Rheumatism, also Glandular Swellings, Consumption, Anæmia, Rickets, Hay Fever, Inflamed or Swollen and Tender Feet, the Enervating Effect of Tropical Climates, Insomnia, Spinal or Muscular and General Weakness, Indigestion, Want of Tone, Weak Ankles, Infantile Paralysis, Bow-legs, Lassitude, &c., &c. Baths of TIDMAN'S SEA SALT have been prescribed and recommended by Dr. MAPOTHER (Professor of Hygiene, Dublin Royal College of Surgeons), Dr. JOHN GAY (Great Northern Hospital), Dr. C. BORLASE CHILDS (City of London Police), Dr. R. BARNES (Finsbury-square), Dr. ARTHUR HILL HASSALL (LANCET Sanitary Commission), Dr. G. H. ELLIOTT (Chichester), Dr. WM. ALLINGHAM (British Orphan Asylum), Dr. THOMAS BROWN (Finsbury-circus), Dr. H. J. HARDWICKE (Sheffield Public Hospital), Dr. BUXTON SHILLITOE (Finsbury-circus), Dr. EDWARD DEWEES (Coventry), and many others. Their letters can be seen on application.

TIDMAN'S SEA SALT is supplied in Bags—1 cwt., 10s.; $\frac{1}{2}$ cwt., 5s. 6d.; $\frac{1}{4}$ cwt. (Box or Bag), 3s., carriage paid to any part of the United Kingdom; also in Packets and Boxes from 1d. upwards.

KEROL

KEROL combines all the properties which go to the making of an ideal preparation.

It has been shown to be practically non-toxic, non-irritant and non-corrosive—a combination of properties which make it the one preparation which can be used with perfect confidence wherever the use of either a disinfectant or antiseptic is indicated. It is of high and definite germicidal value and is perfectly homogeneous

KEROL is highly recommended by Bacteriologists and by prominent members of the Medical Profession.

KEROL CAPSULES

INTESTINAL. These are of great value where intestinal antiseptics is indicated. In a comparatively short space of time the coli content of the intestine is reduced by over 99 per cent. They are non-irritant and perfectly safe.

STOMACHIC. For use in cases of stomach fermentation and other gastric troubles, and are of great value in reducing the number of malign organisms prior to administration of treatment with lactic ferments, i.e., sour milk, etc.

UNIVERSITY OF BIRMINGHAM.

Vice-Chancellor—Professor GILBERT BARLING, M.Sc., F.R.C.S.

Principal—Sir OLIVER LODGE, M.Sc., D.Sc., LL.D., F.R.S.

FACULTY OF MEDICINE.

The SUMMER SESSION opens on TUESDAY, APRIL 27th, 1915.

The WINTER SESSION opens on TUESDAY, OCTOBER 5th, 1915.

Instruction is given in all the main branches of Medical and Dental Science, as under :—

MEDICINE AND SURGERY.

The University confers the Degrees of Bachelor and Doctor of Medicine (M.B. and M.D.), and of Bachelor and Master of Surgery (Ch.B. and Ch.M.).

The Course for the Bachelors' Degrees extends over five years from the date of entrance as a Medical Student.

The total cost for the five years' curriculum, including Examination and Hospital fees, is £158 2s. 6d., payable in five annual instalments.

CLINICAL INSTRUCTION.

(The General and Queen's Hospitals, Birmingham.)

The Practices of these Hospitals are amalgamated for the purpose of Clinical Instruction, which is carried on under the direction of the University Clinical Board. They present an almost unrivalled field for Clinical work, possessing more than 500 BEDS, treating annually upwards of 8000 IN-PATIENTS and 100,000 OUT-PATIENTS, and as students spend part of their curriculum in each Hospital, they have every opportunity of acquiring a varied, full, and practical knowledge of their professional work.

HOSPITAL APPOINTMENTS.

A large number of Resident appointments in the various local Hospitals are open to qualified Students of the School. There are OVER 50 of these appointments in Birmingham alone.

PUBLIC HEALTH.

The University grants a Degree (B.Sc., Public Health), and a Diploma in Public Health (D.P.H.).

Full Courses of instruction are provided for this Degree and Diploma. Examinations are held annually in March and June.

DENTISTRY.

(University of Birmingham and the Birmingham Dental Hospital.)

The University confers the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery (L.D.S.).

Special Courses of instruction are provided for the whole of the Dental Curriculum.

The Curriculum for the Diploma in Dental Surgery extends over four years, and that for the Degree of B.D.S. over five years, from the date of Registration as a Dental Student.

Excluding Apprenticeship, the total cost for the L.D.S. Curriculum (University, Hospital, and Examination Fees) is £114 15s., and that for the B.D.S. Degree, £149 1s.

The Medical and Dental Curricula are adapted to meet the requirements of students preparing for the Examinations of other Universities and Licensing Bodies.

All Courses and Degrees in the University are open to students of both sexes.

A Prospectus, giving full information respecting the Medical Faculty and School of Dentistry, can be obtained on application to the undersigned.

PETER THOMPSON, M.D., Dean.

UNIVERSITY OF EDINBURGH.

PRINCIPAL—SIR WILLIAM TURNER, K.C.B., D.C.L.,
LL.D., D.Sc., M.B.

*The SUMMER SESSION, 1915, opens on
20th April and closes 2nd July.*

*The WINTER SESSION, 1915-16, opens on
5th October and closes 15th March.*

FACULTY OF MEDICINE.

DEAN—PROFESSOR HARVEY LITTLEJOHN, M.A., B.Sc., M.B., C.M.

The Faculty embraces fifteen Chairs and twenty-seven Lectureships; and attached to these Chairs there are about thirty Assistants and Demonstrators. Instruction is given in all the main branches of Medical Science, viz.:

PROFESSORS.

Chemistry	James Walker, D.Sc., F.R.S.
Zoology	J. Cossar Ewart, M.D.
Botany	Isaac Bayley Balfour, M.D., D.Sc.
Anatomy	Arthur Robinson, M.D., C.M.
Physiology	Sir E. A. Schäfer, LL.D.
Materia Medica	Sir Thomas R. Fraser, M.D., LL.D.
Pathology	J. Lorrain-Smith, M.D.
Bacteriology	James Ritchie, M.A., M.D.
Forensic Medicine	Harvey Littlejohn, M.B., B.Sc.
Public Health	C. Hunter Stewart, M.B., D.Sc.
Medicine	Geo. Lovell Gulland, M.D.
Surgery	Alexis Thomson, M.D., C.M., B.Sc.
Midwifery	Sir J. Halliday Croom, M.D.
Clinical Surgery	Francis Mitchell Caird, M.B., C.M.
Clinical Medicine	Wm. Russell, M.D., Sir Thos. R. Fraser, M.D., Geo. Lovell Gulland, M.D.

UNIVERSITY LECTURERS.

Clinical Surgery	Alexis Thomson, M.D., C.M., C. W. Cathcart, M.B., C.M., J. W. B. Hodsdon, M.D., David Wallace, C.M.G., M.B., C.M., Alexander Miles, M.D., C.M.
Clinical Medicine	Sir R. W. Philip, M.D., J. J. Graham Brown, M.D., F. D. Boyd, C.M.G., M.D.
Clinical Gynaecology	A. H. F. Barbour, M.A., M.D., N. T. Brewis, M.B., C.M.
Systematic Gynaecology	A. H. F. Barbour, M.A., M.D.
Mental Diseases	George M. Robertson, M.B., C.M.
Diseases of the Eye	William G. Sym, M.D.
Clinical Instruction on Diseases of Children	John Thomson, M.D., and Staff of Royal Hospital.
Embryology and Vertebrate Zoology	J. Beard, D.Sc.
Anatomy	E. B. Jamieson, M.D.
Applied Anatomy	Harold J. Stiles, M.B., C.M.
Histology	Harold Pringle, M.D.
Physiological Chemistry	(Vacant).
Experimental Physiology	John Tait, M.D., D.Sc.
Physiology of the Nervous System	A. Ninlan Bruce, M.D., D.Sc.
Experimental Pharmacology	W. C. Sillar, M.D., B.Sc.
Pathology, Practical	A. Murray Drennan, M.B., Ch.B.
Physics	C. G. Knott, M.A., D.Sc.
Diseases of the Larynx, Ear, and Nose	A. Logan Turner, M.D.
Tropical Diseases	D. G. Marshall (Major, I.M.S.)
Medical Entomology and Protozoology	J. H. Ashworth, D.Sc.
Tropical Hygiene	J. B. Young, M.B., D.Sc. (conjointly with Professor).
Diseases of the Skin	Norman Walker, M.D., and Frederick Gardiner, M.D.
Clinical Instruction in Infectious Fevers	Alexander James and Claude B. Ker, M.D.
History of Medicine	J. D. Comrie, M.A., B.Sc., M.D.
Neurology	J. J. Graham Brown, M.D.
Physical Methods in the Treatment of Disease	Harry Rainy, M.D.
Surgical Pathology	J. M. Graham, M.B., Ch.B.
Practical Anaesthetics	(Vacant).

Practical Instruction is afforded, under the superintendence of the Professors, in Laboratories, with the necessary appliances, and in Tutorial and Practical Classes connected with the above Chairs, and opportunities are afforded to Students and Graduates to extend their practical knowledge and engage in original research.

Opportunities for Hospital Practice are afforded at the Royal Infirmary, the Hospital for Sick Children, Maternity Hospital, the City Fever Hospital, and the Asylum for the Insane. Upwards of 2160 beds are available for the Clinical Instruction of Students of the University.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh, viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.); and Diplomas in Special Branches of Medical and Surgical Practice may also be conferred on Graduates in Medicine and Surgery of the University.

The minimum Class Fees for M.B. and Ch.B., including Hospital Fee (£12), amount to about £130, and the Matriculation and Examination Fees to £28 7s. An additional Fee of £15 15s. is payable by those who proceed to M.D., and £15 15s. by those who proceed to Ch.M.

The annual value of the Bursaries, Prizes, Scholarships, and Fellowships in the Faculty of Medicine amounts to about £3600, and that of

UNIVERSITY OF EDINBURGH—(Continued).

the other Bursaries, &c., tenable by Students of Medicine, amounts to about £1820.

Instruction is also given in Public Health, and the Degrees of B.Sc. and D.Sc. in Public Health are conferred by the University.

A Syllabus and further information as to Matriculation, the Curricula of Study for Degrees, &c., may be obtained from the Dean of the Faculty of Medicine, and for Degrees in the Faculties of Arts, Science, Divinity, Law, and Music, from the Deans of these Faculties, or from the Clerk of Senatus; and full details are given in the University Calendar, published by James Thin, 55, South Bridge, Edinburgh. Price by post, 3s. 6d.

By Authority of the Senatus.

L. J. GRANT,
Secretary of Senatus.

March, 1915.

Royal College of Surgeons of EDINBURGH. (Incorporated 1505.)

Alcohol and Drug Inebriety and Neurasthenia. INVERNITH SANATORIUM, COLINSBURGH, FIFE, SCOTLAND.

(Licensed under the Inebriates Acts.)

FOR GENTLEMEN ONLY.

(Under the direction of an Advisory Council of eminent Medical Men.)

NEURASTHENIA is treated on approved principles, and there are Open-air Shelters in the grounds for suitable cases. INEBRIETY and NARCOMANIA are treated on definite medical lines, and the most approved scientific means are employed in the curative treatment. The Resident Medical Superintendents have each patient under their personal care and observation. The curative treatment is much aided by the healthy situation of the Sanatorium and by its isolation from temptation. The Sanatorium stands 450 feet above the sea, faces south, and looks out over the Firth of Forth. The climate is dry and bracing. All out-door and in-door sports. First-class private golf course. Excellent mixed shooting over 1600 acres, fishing, tennis, gardening, carpentry, &c. Billiard room (two tables), music room, large private library. References to leading physicians in the chief centres given on application. For all particulars of Invernith Sanatorium, Ltd., apply to the Resident Medical Superintendent, W. H. BRYCE, M.B., C.M. Telegrams: "Salubrious," Upper Largo. Telephone No 8, Upper Largo. Station—Kilconquhar (N. B. Railway).

NORWOOD SANATORIUM, LTD.

REMOVED TO

THE MANSION, BECKENHAM PARK, KENT.

therapeutics of Inebriety upon a definite scientific basis. The treatment is of such a nature that the restrictions common to Retreats need not be enforced. In many cases a residence of six weeks is sufficient. The Sanatorium consists of a large family mansion, recently redecorated and brought up-to-date in all respects. It is situated in a large and beautifully wooded private park in near proximity to London. All information to be obtained from the Resident Medical Superintendent. Consultations at 13, Welbeck-street, W., every afternoon by appointment.

Telegrams: "NOROTORIUM, BECKENHAM."

Resident Medical Superintendent: FRANCIS HARE, M.D.

Telephone: 648 BROMLEY.

NEWMAINS RETREAT, NEWMAINS, LANARKSHIRE.

Licensed under the Inebriates Acts.

The House is devoted to the Care of LADIES of the upper classes only, who can be treated either under the Acts or as Voluntary Patients. The place stands high and the estate is extensive, with bracing air and in good shelter. It is very retired and beautiful, well situated for the treatment of inebriety, narcomania and other perversions, neurasthenia, hysteria, and minor mental ailments.

No patients under certificate of insanity can be received.

References: Sir THOMAS CLOUSTON, Dr. YELLOWLEES, Dr. RISIEN RUSSELL, and others.

Terms and particulars on application to "Superintendent, The Retreat, Newmains, Lanarkshire." Nearest station, Hartwood, Cal. Rly.

INEBRIETY. DALRYMPLE HOUSE, RICKMANSWORTH, HERTS.

For the treatment of Gentlemen under the Act and privately. Established 1833 by an association of prominent medical men and others for the study of inebriety; profits, if any, are expended on the institution. Large secluded grounds on the bank of the river Colne. All kinds of out-door and in-door recreations and pursuits. Terms from 3 guineas weekly.—For particulars, apply to F. S. D. Hogg, M.R.C.S., &c., Resident Medical Superintendent. Telephone: 16 Rickmansworth.

April 7th. Duties commence April 26th.

Hamlet of Mile End Old Town.—
The Guardians of the Poor of the Hamlet of Mile End Old Town
are prepared to receive applications from gentlemen desirous of being
appointed to either of the following offices, for a period of twelve months
at the Infirmary:—
TWO ASSISTANT MEDICAL OFFICERS. Salary £275 per annum,
with board, lodging, and washing.
Applicants must be registered medical practitioners.
The duties may be ascertained upon application to the Medical
Superintendent, who may be interviewed any day (except Saturdays)
before 1 o'clock P.M., and from whom also forms of application may be
obtained, which must be returned to the undersigned not later than the
first post on Monday, the 5th April, 1915.
The appointments will be made subject to the consent of the Local
Government Board and to the provisions of the Poor-law Officers'
Superannuation Act, 1896.
Canvassing the Guardians is prohibited and will be deemed a dis-
qualification.
By order.
BENJAMIN CATMUR, Clerk to the Guardians.
Guardians' Offices, Bancroft-road, Mile End, E., 18th March, 1915.

Lancashire County Council.—Elswick
SANATORIUM, near Kirkham.—Appointment of MEDICAL
SUPERINTENDENT.—The Lancashire County Council are prepared
to receive applications for the post of Medical Superintendent for the
above Institution at the salary of £300 per annum, rising to £350 by
annual increments of £25, together with board, furnished apartments,
and washing.
Applicants must be registered medical practitioners, between twenty-
seven and forty-five years of age, and must have held house appoint-
ments for at least six months in a General Hospital, and have had
special practical experience in the administrative work of a Tuberculosis
Sanatorium and the treatment of Tuberculosis. Special practical expe-
rience in Bacteriology and in the use of Tuberculin will be deemed
important qualifications for the post.
Applications, on forms to be provided, accompanied by copies of three
recent testimonials, to be delivered to the undersigned not later than
the first post on the 15th April, 1915.
Form of application, terms of appointment, and list of duties can be
obtained from the undersigned.
All letters must be marked on the outside "Appointment of Medical
Superintendent."
HARCOURT E. CLARE, Clerk of the County Council.
County Offices, Preston.

Kent County Council.—Appointment
of TUBERCULOSIS OFFICER.—Applications are invited by
the Kent County Council for the position of Tuberculosis Officer.
Candidates must be registered medical practitioners and must have
held a house appointment for at least six months in a General Hospital,
and have had special practical experience in the Diagnosis and Treat-
ment of Tuberculosis.
The candidate appointed will be attached to the County Health
Department, and will be required to work under the direction of the
County Medical Officer, and to devote the whole of his time to the
duties of the office. He will also be required to reside in such part of
the County as may be directed.
The appointment will be subject to three months' notice on
either side.
The salary to be paid will be at the rate of £500 per annum, together
with subsistence and travelling expenses.
Applications, stating age, and earliest date upon which duties could
be commenced, and accompanied by three recent testimonials, must be
received by the undersigned not later than Wednesday, April 7th, 1915.
The appointment is not a temporary one and no forms of application
are issued.
(Signed) ALFRED GREENWOOD, M.D., B.Sc., D.P.H.,
County Medical Officer and Chief Tuberculosis Officer
Sessions House, Maidstone, 24th March, 1915.

County Borough of Croydon.—

CROYDON BOROUGH HOSPITAL.—Notice is hereby given that the Council are prepared to receive applications for the appointment of **ASSISTANT RESIDENT MEDICAL OFFICER** at the Croydon Borough Hospital (170 beds) for Infectious Diseases (including tuberculosis). Preference will be given to candidates who have held previous Hospital appointments.

The salary will be £150 per annum, with board, residence, and laundry at the Hospital, subject to an annual percentage deduction in accordance with the provisions of the Superannuation Scheme adopted by the Council under the powers of the Croydon Corporation Act, 1893.

Applications, stating qualifications and experience, to be sent to me with copies (not originals) of not more than three testimonials of recent date.

JOHN M. NEWNHAM, Town Clerk.

The Town Hall, Croydon, 24th March, 1915.

With a bonus in each case of £5 per month during the continuance of the war.

The appointments are for six months, with board and residence. Candidates must be registered under the Medical Act.

Applications, stating age, together with copies of testimonials and certificates of registration, to be addressed to the undersigned without delay.

By order of the Board.

GEORGE RUDDLE,

Secretary and Superintendent.

March 24th, 1915.

Bradford Poor-law Union.—Assistant

RESIDENT MEDICAL OFFICER (Lady or Gentleman).—Wanted, an Assistant Resident Medical Officer for the St. Luke's Hospital and Union House of the above Union.

Salary £200, with rations, apartments, and washing.

The appointment will be for one year. Candidates must be duly qualified, unmarried, and the person appointed must act under the direction of the Medical Officer and the regulations of the Guardians.

The St. Luke's Hospital is divided into Medical and Surgical Wards, and facilities are provided for Pathological and Bacteriological work.

Applications, giving age and full particulars of experience and qualifications, accompanied by testimonials of character and ability, to be sent to me by March 31st.

By order.

GEORGE M. CROWTHER, Clerk to the Guardians.

Union Offices, 22, Manor-row, Bradford, 24th March, 1915.

West Ham Union.—The Guardians

invite applications for the following appointments:—

At their Sick Home, 95, Forest-lane, Forest Gate, E.—**DEPUTY MEDICAL OFFICER**, at a salary of £250 per annum, with the usual residential allowances. Further particulars may be obtained upon application to the Medical Officer at the Home.

At their Workhouse, Union-road, Leytonstone, N.E.—**LADY ASSISTANT MEDICAL OFFICER**, at a salary of £140 per annum, rising by annual increments of £10 to a maximum of £160 per annum, with the usual residential allowances. Further particulars may be obtained upon application to the Medical Officer at the Workhouse.

The successful candidates will be required, should occasion arise, to act at any other Institution under the control of the Board.

Forms, upon which application must be made, can be obtained at my office, or will be forwarded upon receipt of a stamped, addressed foolscap envelope, and must be returned not later than 10 A.M. on Thursday, the 1st proximo.

Canvassing the Guardians, either directly or indirectly, is prohibited and will disqualify.

By order of the Board.

THOMAS SMITH, Clerk

Board Room, Union-road, Leytonstone, N.E., 23rd March, 1915.

Croydon Union.—Assistant Medical

SUPERINTENDENT of the INFIRMARY and ASSISTANT MEDICAL OFFICER of the WORKHOUSE and CHILDREN'S HOMES.—The Guardians of the above-named Union invite applications for the appointment of Assistant Medical Superintendent of the Infirmary and Assistant Medical Officer of the Workhouse and Children's Homes.

Candidates for this appointment must be not under twenty-five years of age, and be qualified by law to practise both Medicine and Surgery in England and Wales, such qualification being established by the production to the Guardians of a diploma, certificate of a degree, licence, or other instrument granted or issued by a competent legal authority in Great Britain or Ireland, testifying to the medical and surgical qualifications of the candidate.

Candidates must have had experience in Institution work and Operative Surgery.

Salary £225 per annum, rising at the end of the first year to £250 per annum, with the usual residential allowances at the Infirmary, Mayday-road, Thornton Heath.

Forms of application, with particulars of duties, can be obtained of the undersigned.

Applications, in candidates' own handwriting, must reach me not later than the first post on Tuesday, the 6th April next.

Selected candidates will have notice to attend on the 13th April.

Personally canvassing the Guardians will be deemed a disqualification.

By order.

HARRY LIST, Clerk to the Guardians.
